Squid 2.6 Configuration Manual

Support and Queries to E-mail squid_support@visolve.com

Disclaimer: This manual is NOT a Squid tutorial. It does not, for example, takes the reader through step-by-step details of Squid installation and configuration. The objective of this manual is to explain, in as much detail as possible, every configuration parameter available in Squid 3.0. As such, the reader is required to have prior knowledge of basic Squid installation and configuration. The details presented in this manual are in the nature of reference material. For a complete tutorial on Squid, please visit http://www.squid-cache.org

NETWORK PARAMETERS

Network parameters control network configuration, e.g. communication ports, secure network access and options, SSL options, inter-cache communication, multicast ICP queries etc.

Synopsis

This parameter allows the user to define the address on which Squid will listen for client's http requests. This is a required parameter, and there are no defaults. Without this configuration, Squid will never start.

Arguments

port	Port to which Squid will bind the socket
hostname	hostname to which Squid will bind the socket
ip_address	ip_address to which Squid will bind the socket

When a hostname or IP address is specified (as shown in variations 2 and 3 above), Squid binds the socket to that specific address.

Note: The http_port parameter may be specified multiple times, with different addresses each time. This will cause Squid to listen on multiple ports.

Options are arguments that further control the behavior of the Squid proxy. The supported values are explained in the table below:

Options	Functions
transparent	Support for transparent interception of outgoing requests without browser settings
accel	Accelerator mode. Also needs at least one of vhost/vport/defaultsite.
defaultsite=	Main web site name for accelerators. Implies accel.
vhost	Accelerator using the Host header for virtual domain support.
vport	Accelerator using the Host header for virtual domain support.
vport=	As above, but uses specified port number rather than the http_port number.
urlgroup=	Default urlgroup to mark requests with.
protocol=	Protocol to reconstruct accelerated requests with. Defaults to http.
no-connection- auth	Prevent forwarding of Microsoft connection oriented authentication.
tproxy	Support Linux TPROXY for spoofing outgoing connections using the client IP address.

Example(s)

http_port 3128

http_port 172.16.1.53:3300 http_port 172.16.1.53:80 accel defaultsite=visolve.com

http_port 3128 transparent

TAG NAME	https_port
Description	Port where Squid will listen for clients https requests
Build Option	enable-ssl
Usage	https_port [ip:]port cert=certificate.pem key=key.pem] [options]
Default	none

This parameter specifies the address where Squid will listen for client's https requests. Its role is significant when Squid is configured in accelerator mode where SSL works to be done.

Arguments

ip	IP Address to which Squid will bind the socket
port	Port to which Squid will bind the socket
cert=certificate.pem	Path and the file name where SSL certificate is located
key=key.pem	Path and the file name where SSL private key for the certificate is located

options controls other additional features and are explained in the table below:

accel	Accelerator mode. Also needs at least one of defaultsite or vhost.
defaultsite=	The name of the https site presented on this port
vhost	Domain based virtual host support. Useful in combination with a wildcard certificate or other certificates valid for more than one domain. Implies accel.
urlgroup=	Default urlgroup to mark requests with
protocol=	Protocol to reconstruct accelerated requests with. Defaults to https.
cert=	Path to SSL certificate (PEM format)
key=	Path to SSL private key file (PEM format) if not specified, the certificate file is assumed to be a combined certificate and key file
version=	The version of SSL/TLS supported 1 automatic (default) 2 SSLv2 only 3 SSLv3 only 4 TLSv1 only
cipher=	Colon separated list of supported ciphers
options=	Various SSL engine options. The most important being: NO_SSLv2 Disallow the use of SSLv2 NO_SSLv3 Disallow the use of SSLv3 NO_TLSv1 Disallow the use of TLSv1 SINGLE_DH_USE Always create a new key when using temporary/ephemeral DH key exchanges
	See src/ssl_support.cc or OpenSSL SSL_CTX_set_options documentation for a complete list of options.
clientca=	File containing the list of CAs to use when requesting a client certificate
cafile=	File containing additional CA certificates to use when verifying client certificates. If unset clientca will be used.
capath=	Directory containing additional CA certificates to use when verifying client certificates
dhparams=	File containing DH parameters for temporary/ephemeral DH key exchanges
sslflags=	Various flags modifying the use of SSL: DELAYED_AUTH - Don't request client certificates immediately, but wait until acl processing requires a certificate NO_DEFAULT_CA - Don't use the default CA list built in to OpenSSL. NO_SESSION_REUSE - Don't allow for session reuse. Each connection will result in a new SSL session. VERIFY_CRL - Verify CRL lists when accepting client certificates VERIFY_CRL_ALL - Verify CRL lists for all certificates in the client certificate chain
sslcontext=	SSL session ID context identifier.

Example(s)

Options

Functions

https_port 443 cert=/usr/local/ssl/cert.pem key=/usr/local/ssl/key.pem defaultsite=visolve.com

TAG NAME	ssl_unclean_shutdown
Description	Used to handle bugs in browsers which does not fully support SSL
Build Option	enable-ssl
Usage	ssl_unclean_shutdown on off
Default	ssl unclean shutdown off

Synopsis
Some browsers like MSIE will indicate bugs during SSL shutdown. During such conditions, making this tag "on" will handle those bugs.

Arguments

on/off Enable or disable ssl_unclean_shutdown

	TAG NAME	ssl_engine
	Description	Defines Hardware SSL acceleration which is to be used
	Build Option	enable-ssl
-	Jsage	ssl_engine engine
	Default	none

Synopsis

The openssl engine to use. For Example(s), you will need to set this if you would like to use hardware SSL acceleration.

Arguments

Hardware SSL accelerator to be used engine

Description	Used to define clients SSL certificate for proxying https:// URLs
Build Option	enable-ssl
Usage	sslproxy_client_certificate path/certificatefile
Default	none

When proxying https:// URLs requests, this tag defines the clients SSL certificate path and the certificate file to be used for verification.

Arguments

11/1	ath/ ertificatefile	Path and the file that holds the clients SSL certificate
------	------------------------	--

Example(s)

sslproxy_client_certificate /usr/local/ssl/cert.pem

TAG NAME	sslproxy_client_key
Description	Defines clients SSL certificate key for proxying https:// URLs
Build Option	enable-ssl
Usage	sslproxy_client_key path/key.pem
Default	none

Synopsis

When Squid is used as a proxy server for https:// URLs requests, this tag defines the clients SSL certificate key's path and the file that holds the key.

Arguments

path/key.pem Path and the file that contains the clients certificate key

Example(s)

sslproxy_client_key /usr/local/ssl/certkey.pem

TAG NAME	sslproxy_version
Description	Defines the SSL version level to be used when proxying https:// URLs
Build Option	enable-ssl
Usage	sslproxy_version version
Default	sslproxy_version 1

Synopsis

When SSL certificate is used for proxying https:// URLs, this tag can be used to define the SSL version level that will be used for handling encrypted connections.

Arguments

version	SSL version level
---------	-------------------

Example(s)

sslproxy_version 3

A	TAG NAME	sslproxy_options
	Description	This defines the SSL engine options to be used when proxying https:// URLs
	Build Option	enable-ssl
	Usage	options option
	Default	none

Synopsis

When proxying https:// URLs, this tag is used to specify various SSL options.

Arguments

option SSL options

Example(s)

sslproxy_options NO_SSLv2

TAG NAME	sslproxy_cipher	
Description	SSL cipher list to be used when proxying https:// URLs	
Build Option	enable-ssl	
Usage	sslproxy_cipher cipher	
Default	none	

Synopsis

This tag sets the ciphers on which SSL will decide during the negotiation phase of the SSL connection when proxying https:// URLs

Arguments

cipher SSL proxy cipher to be used

Description	Defines the file that contains CA certificate
Build Option	enable-ssl
Usage	sslproxy_cafile filename
Default	none

Synopsis
This tag defines the file that contains CA certificate to be used for verifying server certificates when Squid is used as a proxy server for https://URLs.

Arguments

filename	File that contains CA certificate
----------	-----------------------------------

Example(s) sslproxy_cafile /usr/local/ca1.pem

TAG NAME	sslproxy_capath
Description	Defines the directory for the file containing CA certificate
Build Option	enable-ssl
Usage	sslproxy_capath path
Default	none

Synopsis
While proxying https:// URLs, this tag defines the path where the CA certificate file to be used when verifying server certificates is located.

Arguments

path	Path where CA certificate file is located

Example(s)

sslproxy_capath /usr/local/

TAG NAME	sslproxy_flags
Description	Specifies the way how SSL should act while proxying https:// URLs
Build Option	enable-ssl
Usage	sslproxy_flags flags
Default	none

Synopsis

When Squid is used as a proxy server for https://URLs, this tag is used to defines the nature of SSL's behaviour.

Arguments

Flags	Meaning
DONT_VERIFY_PEER	Accept certificates even if they fail to verify
NO_DEFAULT_CA	Don't use the default CA list built in to OpenSSL
NO_SESSION_REUSE	Don't allow for session reuse. Each connection will result in a new SSL session.
VERIFY_CRL	Verify CRL lists when accepting client certificates
VERIFY_CRL_ALL	Verify CRL lists for all certificates in the client certificate chain

Example(s) sslproxy_flags NO_DEFAULT_CA

TAG NAME	sslpassword_program
Description	Specify a program used for entering SSL key passphrases when using encrypted SSL certificate keys.
Build Option	enable-ssl
Usage	sslpassword_program program
Default	none

Synopsis

Specify a program used for entering SSL key passphrases when using encrypted SSL certificate keys. If not specified keys must either be unencrypted, or Squid started with the -N option to allow it to query interactively for the passphrase.

Arguments

program	Program used for entering the SSL key passphrase

Example(s)

sslpassword_program /usr/local/program

TAG NAME	icp_port	

Description	Port number through which Squid sends and receives ICP queries
Build Option	Default
Usage	icp_port portnumber
Default	icp_port 0

Defines the port for ICP packets to be sent and received from neighbour caches.

Arguments

portnumber	Port to which Squid will bind the socket
------------	--

Example(s)

icp_port 3030

TAG NAME	htcp_port
Description	Port number through which Squid sends and receives HTCP queries
Build Option	enable-htcp
Usage	htcp_port portnumber
Default	htcp_port 4827

Synopsis

This tag defines the port address through which HTCP packets will be sent and received from neighbour caches.

Arguments

	portnumber	Port to which Squid will bind the socket
--	------------	--

Example(s)

htcp_port 2134

TAG NAME	mcast_groups
Description	Defines list of multicast groups which your server should join to receive multicasted ICP queries
Build Option	Default
Usage	mcast_groups ip_address
Default	none

Synopsis

Multicast is essentially the ability to send one IP packet to multiple receivers. Your server will join to the multicat groups defined by the IP Addresses.

This option is to be set only if you want to RECEIVE multicast queries.

ICP replies are always sent via unicast, so this option does not affect whether or not you will receive replies from multicast group members.

Arguments

ip_address	ip_address of the multicast groups to join
------------	--

Example(s)

mcast_groups 239.128.16.128 224.0.1.20

TAG NAME	udp_incoming_address, udp_outgoing_address
Description	Defines the address for sending and receiving ICP packets
Build Option	Default
Usage	udp_incoming_address ip_address udp_outgoing_address ip_address
Default	udp_incoming_address 0.0.0.0 udp_outgoing_address 255.255.255

Synopsis

These tags defines the interface through which ICP packets are sent and received. The default behavior is to not bind to any specific address.

A udp_incoming_address value of 0.0.0.0 indicates that Squid should listen for UDP messages on all available interfaces.

If udp_outgoing_address is set to 255.255.255.255 (the default) then it will use the same socket as udp_incoming_address. Only change this if you want to have ICP queries sent using another address than where this Squid listens for ICP queries from other caches.

Arguments

ip_address | ip_address to which Squid binds the ICP socket

Note: udp_incoming_address and udp_outgoing_address cannot have the same value since they both use port 3130.

Example(s)

udp_incoming_address 192.168.1.35 udp_outgoing_address 192.168.150.6

NEIGHBOUR SELECTION ALGORITHM

Configurations needed for communication of Squid with the neighbor caches are done under this category.

Description	This specifies other caches in cache hierarchy
Build Option	Default
Usage	cache_peer hostname type http_port icp_port [options]
Default	none

Synopsis
This defines how to treat the neighbour peer's in cache hierarchy. This is used during inter cache communication.

Arguments

hostname	The cache peer to which communication is to be established
type	The way how the cache peer be treated (either as 'parent', 'sibling' or 'multicast').
proxy_port	Port number where the cache listens for other peers requests.
icp_port	Used for querying neighbor caches about objects. To have a non-ICP neighbor specify '7' for the ICP port and make sure the neighbour machine has the UDP echo port - enabled in its /etc/inetd.conf file.

Options	Functions
proxy-only	to specify that objects fetched from this cache should not be saved locally.
weight=n	to specify a weighted parent. The weight must be an integer. The default weight is 1, larger weights are favored more.
basetime=n	to specify a base amount to be subtracted from round trip times of parents. It is subtracted before division by weight in
	calculating which parent to fetch from. If the rtt is less than the base time then the rtt is set to a minimal value.
ttl=n	to specify a IP multicast TTL to use when sending an ICP queries to this address. Only useful when sending to a multicast
	group. Because we don't accept ICP replies from random hosts, you must configure other group members as peers with the
	multicast-responder' option below.
no-query	NOT to send ICP queries to this neighbor.
default	if this is a parent cache which can be used as a "last-resort." You should probably only use 'default' in situations where you cannot use ICP with your parent cache(s).
round-robin	to define a set of parents which should be used in a round-robin fashion in the absence of any ICP queries.
multicast-responder	indicates that the named peer is a member of a multicast group. ICP queries willnot be sent directly to the peer, but ICP replies will be accepted from it.
closest-only	indicates that, for ICP_OP_MISS replies, we'll only forward CLOSEST_PARENT_MISSes and never FIRST_PARENT_MISSes.
no-digest	NOT to request cache digests from this neighbor.
no-netdb-exchange	disables requesting ICMP RTT database (NetDB) from the neighbor.
no-delay	to prevent access to this neighbor from influencing the delay pools.
login=user:password	if this is a personal/workgroup proxy and your parent requires proxy authentication. The string can include URL escapes (i.e. %20 for spaces). This also means that % must be written as %%.
login=PASS	if users must authenticate against the upstream proxy. This will pass the users credentials as they are to the
3	peer proxy. This only works for the Basic HTTP authentication scheme. To combine this with proxy auth both proxies must share the same user database as HTTP only allows for
	one proxy login. Also be warned that this will expose your users proxy password to the peer. USE WITH CAUTION
login=*:password	to pass the username to the upstream cache, but with a fixed password. This is meant to be used when the peer is in another administrative domain, but it is still needed to identify each user. The star can optionally be followed by some extra information which is added to the username. This can be used to identify this proxy to the peer, similar to the login=username:password option above.
connect-timeout=nn	to specify a peer specific connect timeout (also see the peer connect timeout directive)
digest-url=url	to tell Squid to fetch the cache digest (if digests are enabled) for this host from the specified URL rather than the Squid default location.
allow-miss	to disable Squid's use of only-if-cached when forwarding requests to siblings. This is primarily useful when icp_hit_stale is used by
allow-fillss	the sibling. To extensive use of this option may result in forwardingloops, and you should avoid having two-way peerings with this option. (for Example(s) to deny peer usage on requests from peer by denying <u>cache_peer_access</u> if the source is a peer)
max-conn	to limit the amount of connections Squid may open to this peer.
htcp	to send HTCP, instead of ICP, queries to the neighbor. You probably also want to set the "icp port" to 4827 instead of 3130.
htcp-oldsquid	to send HTCP to old Squid versions
carp-load-factor	to define a parent cache as one participating in a CARP array.
originserver	causes this parent peer to be contacted as a origin server. Meant to be used in accelerator setups.
userhash	to load-balance amongst a set of parents based on the client proxy_auth or ident username.
sourcehash	
name=xxx	to load-balanse amongs a set of parents based on the client source ip. if you have multiple peers on the same host but different ports. This name can then be used to differentiate the peers in
	cache_peer_access and similar directives.
monitorurl=url	to have periodically request a given URL from the peer, and only consider the peer as alive if this monitoring is successful
monitorsize=sizespec	to limit the size range of 'monitorurl' replies considered valid.
monitorinterval=seconds	to change frequency of how often the peer is monitored with 'monitorurl'
monitortimeout=seconds	to change the timeout of 'monitorurl'. Defaults to 'monitorinterval'.
group=name	Group Name of the peer-cache
forceddomain=name	to forcibly set the Host header of requests forwarded to this peer. Useful in accelerator setups where the server (peer) expects a certain domain name and using redirectors to feed this domainname is not feasible.
ssl	to indicate that connections to this peer should bs SSL/TLS encrypted.
sslcert= /path/to/ssl/certificate	to specify a client SSL certificate to use when connecting to this peer.
sslkey= /path/to/ssl/key	to specify the private SSL key corresponding to sslcert above. If 'sslkey' is not specified then 'sslcert' is assumed to reference a combined file containing both the certificate and the key.
sslversion=1 2 3 4	to specify the SSL version to use when connecting to this peer 1 = automatic (default) 2 = SSL v2 only 3 = SSL v3 only 4 = TLS v1 only
sslcipher=	to specify the list of valid SSL chipers to use when connecting to this peer
ssloptions=	to specify various SSL engine options NO_SSLv2 Disallow the use of SSLv2 NO_SSLv3 Disallow the use of SSLv3 NO_TLSv1 Disallow the use of TLSv1

· ·	to enable the "Front-End-Https: On" header needed when using Squid as a SSL frontend infront of Microsoft OWA. See MS KB document Q307347 for details on this header. If set to auto then the header will only be added if the request is forwarded as a https://URL.
connection-auth[=on off auto]	to tell Squid that this peer does not support Microsoft connection oriented authentication, and any such challenges received from there should be ignored.

Example(s)

cache_peer proxy.visolve.com parent 3128 3130 default cache_peer 172.16.1.57 parent 3128 3130 proxy-only cache_peer 172.16.1.123 sibling 3129 5500 weight=2

TAG NAME	cache_peer_domain
Description	Used to limit the domains for which a neighbour cache will be queried
Build Option	Default
Usage	cache_peer_domain cache-host domain [domain]
Default	none

Synopsis

In case if there are more number of cache peers, then using this tag we can direct the query to that cache peer for particular domains alone.

Prefixing the domain with "!" will be queried for objects NOT in that domain.

Arguments

cache-host	The cache peer to be queried for the specified domain
domain	The domain for which the cache peer to be queried

Example(s)

cache_peer_domain 172.16.1.57 .co.in

TAG	NAME	neighbor_type_domain
Descriptio	n	Using this tag, we can modify the define nerighbour type for particular domains
Build Option	on	Default
Usage		neighbor_type_domain neighbour parent sibling domain domain
Default		none

Synopsis

There may be situations where an already defined neighbour to be treated differently for particular domains alone. This can be achieved using this directive.

Arguments

neighbour	The neighbour which to be treated diffrently
parent sibling	How the neighbour to be treated (parent/sibling)
domain	The domain for which the cache peer to be treated differently

Example(s)

cache_peer parent 172.16.1.57 3128 3130 neighbor_type_domain 172.16.1.57 sibling.com

TAG NAME	icp_query_timeout
Description	Used to define the inter-cache query timeout
Build Option	Default
Usage	icp_query_timeout time(msec)
Default	icp_query_timeout 0

Synopsis

Based on the round trip time of recent ICP queries, Squid normally determines an optimal ICP query timeout. If you want to override this value, you can specify the timeouts using this tag.

The value specified is in Milliseconds.

Arguments

time Fixed time period for ICP queries

Example(s)

icp_query_timeout 2000

TAG NAME	maximum_icp_query_timeout
Description	Defines ICP query timeout value to a maximum limit
Build Option	Default
Usage	maximum_icp_query_timeout time(msec)
Default	maximum_icp_query_timeout 2000

Normally the ICP query timeout is determined dynamically. But sometimes it can lead to very large values (say 5 seconds). Use this option to put an upper limit on the dynamic timeout value.

The value specified is in Milliseconds.

Note: Do NOT use this option to always use a fixed (instead of a dynamic) timeout value. To set a fixed timeout see the top query timeout directive.

Arguments

time Maximum upper time limit

Example(s)

maximum_icp_query_timeout 4000

TAG NAME	minimum_icp_query_timeout
Description	Defines ICP query timeout value to a minimum limit
Build Option	Default
Usage	minimum_icp_query_timeout time(msec)
Default	minimum_icp_query_timeout 5

Synopsis

As in the previous tag, ICP query timeouts to very small value, even lower than the normal latency variance on your link due to traffic. Use this option to put an lower limit on the dynamic timeout value.

The value specified is in Milliseconds.

Note: Do NOT use this option to always use a fixed (instead of a dynamic) timeout value. To set a fixed timeout see the <u>icp_query_timeout</u> directive.

Arguments

time Minimum lower time limit

Example(s)

minimum_icp_query_timeout 4000

TAG NAME	mcast_icp_query_timeout
Description	In case of multicast peer's, the value specified in this tag determines how long should Squid wait to count all replies from its peers
Build Option	Default
Usage	mcast_icp_query_timeout time(msec)
Default	mcast_icp_query_timeout 2000

Synopsis

For Multicast peers, Squid regularly sends out ICP "probes" to count how many other peers are listening on the given multicast address. This tag determines the time how long Squid should wait to count all replies from its peers.

The value specified is in Milliseconds.

Arguments

time Time period to wait

Example(s)

mcast_icp_query_timeout 3000

TAG NAME	dead_peer_timeout
Description	Defines the time period after which Squid will declare the corresponding peer as dead
Build Option	Default
Usage	dead_peer_timeout time(sec)
Default	dead_peer_timeout 10 seconds

Synopsis

This allows Squid to define the time period for declaring a peer cache as "dead." If there are no ICP replies received with in the specified amount of time, Squid will declare that peer as dead and will not expect to receive any further ICP replies. However, it continues to send ICP queries, and will mark the peer as alive upon receipt of the first subsequent ICP reply.

Note

This timeout also affects when Squid expects to receive ICP replies from peers. If more than dead_peer seconds have passed since the last ICP reply was received, Squid will not expect to receive an ICP reply on the next query. Thus, if your time between requests is greater than this timeout, you will see a lot of requests sent DIRECT to origin servers instead of to your parents.

Arguments

time Time period to decide the cache peer as dead

Example(s)

dead_peer_timeout 50 seconds

TAG NAME hierarchy_stoplist

Description	Use this tag not to query neighbour caches for certain objects
Build Option	Default
Usage	hierarchy_stoplist words
Default	none

Certain words defined in this tag when matched in the URLs, directs Squid not to query neighbour caches.

Arguments

words Words to be matched for direct access

Example(s)

hierarchy_stoplist cgi-bin?

TAG NAME	cache [previously called as no_cache]
Description	Use this to force certain objects to never be cached
Build Option	Default
Usage	cache allow deny acl
Default	none

Synopsis

A list of ACL elements which, if matched, cause the request not to be satisfied from the cache and the reply not to be cached. In other words, use this to force certain objects to never be cached.

You must use the word 'DENY' to indicate the ACL names which should NOT be cached.

Arguments

allow/deny	Allow or deny caching of objects on matching the acl
acl	The condition/rule to be matched for which caching of those objects can be allowed or denied

Example(s)

acl QUERY urlpath_regex cgi-bin \? cache deny QUERY

TAG NAME	cache_vary
Description	Enables the caching of vary:in objects
Build Option	Default
Usage	cache_vary on off
Default	cache_vary on

Synopsis

Set to off to disable caching of Vary:in objects.

This is URL's where the server response varies depending to the capabilites and preferences of the browser.

Arguments

Enable or Disable the vary on/off

TAG NAME	broken_vary_encoding
Description	This replies matching this access list will have the cache split replies matching this access list will have the cache split ETag to be unique.
Build Option	Default
Usage	broken_vary_encoding allow deny [!]aclname
Default	acl apache rep_header Server ^Apache broken_vary_encoding allow apache

Synopsis

Many servers have broken support for on-the-fly Content-Encoding, returning the same ETag on both plain and gzip:ed variants. Vary replies matching this access list will have the cache split on the Accept-Encoding header of the request and not trusting the

You must use the word 'DENY' to indicate the ACL names which should NOT be cached.

Arguments

allow/deny	Allow or deny the broken vary encoding on matching the acl
acl	The condition/rule to be matched for which encoding can be allowed or denied

Example(s)

acl apache rep_header Server ^Apache broken_vary_encoding allow apache

OPTIONS WHICH AFFECT THE CACHE SIZE

Tags under this section deals with cache memory configurations like cache memory size, swap size, maximum and minimum object size, cache and memory replacement policies.

TAG NAME cache_mem

Description	cache_mem defines the ideal amount of memory to be used for In-Transit objects, Hot Objects, Negative-Cached objects
Build Option	Default
Usage	cache_mem size
Default	cache_mem 8 MB

Data for these objects are stored in 4 KB blocks. This parameter specifies the ideal upper limit on the total size of 4 KB

In-transit objects have priority over the others. When additional space is needed for incoming data, Negative-cached and Hot objects will be released. In other words, the negative-cached and hot objects will fill up any unused space not needed for In-

If circumstances require, this limit will be exceeded. Specifically, if your incoming request rate requires more than cache_mem of memory to hold In-transit objects, Squid will exceed this limit to satisfy the new requests. When the load decreases, blocks will be freed until the high-water mark is reached. Thereafter, blocks will be used to store hot objects.

Note

This tag does not specify the maximum process size. It places a limit on one aspect of squid's memory usage. Squid uses memory for other things as well. Process will probably become twice or three times bigger than the value put here.

Arguments

size Cache memory size

Example(s)

cache_mem 32 MB

TAG NAME	cache_swap_low, cache_swap_high
Description	This defines low- and high-water marks for cache object replacements
Build Option	Default
Usage	cache_swap_low percent(0-100) cache_swap_high percent(0-100)
Default	cache_swap_low 90 cache_swap_high 95

Synopsis

This tags define when the replacement should take place. Replacement begins when the swap (disk) usage is above the lowwater mark and attempts to maintain utilization near the low-water mark. As swap utilization gets close to high-water mark object eviction becomes more aggressive. If utilization is close to the low-water mark less replacement is done each time.

Defaults are 90% and 95%. If you have a large cache, 5% could be hundreds of MB. If this is the case you may wish to set these numbers closer together.

Arguments

low and high level in percentage percent

Example(s)

cache_swap_low 50 cache_swap_high 75

TAG NAME	maximum_object_size	
Description	Defines maximum size for objects to be stored in the disk	
Build Option	Default	
Usage	maximum_object_size size	
Default	object_size 4096 KB	

Synopsis

Objects larger than this size will NOT be saved on disk. The value is specified in kilobytes, and the default is 4MB. If you wish to get a high BYTES hit ratio, you should probably increase this (one 32 MB object hit counts for 3200 10KB hits). Leave this value low if you wish to increase the speed more than what you want to save bandwidth.

If using the LFUDA replacement policy you should increase this value to maximize the byte hit rate improvement of LFUDA! See replacement_policy below for a discussion of this policy.

Arguments

size Maximum object size

Example(s)

maximum_object_size 320010 KB

TAG NAME	minimum_object_size
Description	Specifies the minimum object size below which will not be saved to the disk
Build Option	Default
Usage	minimum_object_size size
Default	minimum object size 0 KB

Objects smaller than this size will NOT be saved on disk. The value is specified in kilobytes, and the default is 0 KB, which means there is no minimum.

Arguments

Minimum object size size

Example(s)

minimum_object_size 10 KB

Description	Defines maximum size of the object to be kept in memory cache
Build Option	Default
Usage	maximum_object_size_in_memory size
Default	maximum_object_size_in_memory 8 KB

Objects greater than the size specified in this tag will not be kept in the memory cache. This should be set high enough to keep objects accessed frequently in memory to improve performance at the same time low enough to keep larger objects from hoarding cache mem.

Arguments

size	Maximum size of the object to be kept in memory cache

Example(s)

maximum_object_size_in_memory 100 KB

TAG NAME	ipcache_size, ipcache_low, ipcache_high
Description	The size of the cache used for IP addresses and the high and low water marks for the same
Build Option	Default
Usage	<pre>ipcache_size number of entries ipcache_low percent ipcache_high percent</pre>
Default	ipcache_size 1024 ipcache_low 90 ipcache_high 95

Synopsis

Defines the size of cache needed for caching ip address, also its low and high water marks.

Arguments

number of entries	Number of entries to be cached
percent	low and high level for the ipcache in percentage

Example(s)

ipcache_size 2048 ipcache_low 90 ipcache_high 95

TAG NAME	fqdncache_size	
Description	Defines the size of in memory cache needed for fully qualified domain names	
Build Option	Default	
Usage	fqdncache_size number of entries	
Default	fqdncache_size 1024	

Synopsis

This is used to specify maximum number of entries for fully qualified domain names. Defaults to 1024, which is usually a safe value. In environments where DNS queries are slow, raising this may help.

Arguments

number of entries	Number of fully qualified domains to be cached

Example(s)

fqdncache_size 2048

TAG NAME	cache_replacement_policy
Description	The cache replacement policy parameter determines which objects are to be replaced when disk space is needed
Build Option	enable-removal-policy
Usage	cache_replacement_policy policy
Default	cache replacement policy Iru

Synopsis

Whenever space for new objects were not found in the disk, *cache_replacement_policy* tag determines which objects in the cache memory (disk) should be replaced.

The cache replacement policies is of four types. They are,

Policy	Explanation
Iru	Squid's original list based LRU policy
heap GDSF	Greedy-Dual Size Frequency
heap LFUDA	Least Frequently Used with Dynamic Aging
heap LRU	LRU policy implemented using a heap

This applies to any cache_dir lines listed below this.

The Iru policies keeps recently referenced objects.

The heap GDSF policy optimizes object hit rate by keeping smaller popular objects in cache so it has a better chance of getting a hit. It achieves a lower byte hit rate than LFUDA though since it evicts larger (possibly popular) objects.

The heap LFUDA policy keeps popular objects in cache regardless of their size and thus optimizes byte hit rate at the expense of hit rate since one large, popular object will prevent many smaller, slightly less popular objects from being cached.

Both policies utilize a dynamic aging mechanism that prevents cache pollution that can otherwise occur with frequency-based replacement policies.

For more information about the GDSF and LFUDA cache replacement policies see http://www.hpl.hp.com/techreports/1999/HPL-1999-69.html and http://fog.hpl.external.hp.com/techreports/98/HPL-98-173.html.

If using the LFUDA replacement policy you should increase the value of maximum object size above its default of 4096 KB to maximize the potential byte hit rate improvement of LFUDA.

Arguments

One of the above mentioned policies policy

Example(s)

cache_replacement_policy heap LFUDA

TAG NAME	memory_replacement_policy
Description	Specifies the policy for object replacement in memory when space for new objects is not available
Build Option	Default
Usage	memory_replacement_policy policy
Default	memory_replacement_policy Iru

Synopsis

Like cache_replacement_policy, this applies to memory space (RAM) for object replacement when the required space is not available for new objects.

Policies are same as cache replacemen policy.

Arguments

policy One of the policies mentioned in cache_replacement_policy tag

Example(s)

memory_replacement_policy LFUDA

LOG FILE PATH NAMES AND CACHE DIRECTORIES

Squid provides a number of logs that can be used when debugging problems, and when measuring the effectiveness and identifying users and the sites they visit. Because Squid can be used to "snoop" on users browsing habits, one should carefully consider privacy laws in your region and more importantly be considerate to your users. That's being said, logs can be very valuable tools in insuring that your users get the best service possible from your cache.

TAG NAME	cache_dir
Description	This is used to define cache directory, its path, type and size
Build Option	Default
Usage	cache_dir Type Directory-Name FS-specfic-data [options]
Default	cache_dir ufs /usr/local/Squid/var/cache 100 16 256

All objects which are to be cached are stored in the disk space defined by this tag. This defines the path to cache directory, cache directory name, type and size of the cache area.

Arguments			
Туре	Type specifies the kind of storage system to use. Only "ufs" is built by default. To enable any of the other storage systems see theenable-storeio configure option. Type is one of the following: 1. ufs is the old well-known Squid storage format that has always been there. 2. aufs uses the same storage format as ufs, utilizing POSIX-threads to avoid blocking the main Squid process on disk-I/O. This was formerly known in Squid as async-io. 3. diskd uses the same storage format as ufs, utilizing a separate process to avoid blocking the main Squid process on disk-I/O.		
	Туре	Usage	
	ufs	cache_dir ufs Directory-Name Mbytes L1 L2 [options]	
	aufs	cache_dir aufs Directory-Name Mbytes L1 L2 [options]s	
	diskd	cache_dir diskd Directory-Name Mbytes L1 L2 [options] [Q1=n] [Q2=n]	
	coss		
Directory-Name		name is a top-level directory where cache swap files will be stored.If you want to use an entire disk for caching, then this can unt-point directory. The directory must exist and be writable by the Squid process. Squid will NOT create this directory for	
Mbytes	Mbytes is t	the amount of disk space (in MB) to use under this directory. The default is 100 MB. Change this to suit your configuration	
.evel1	Number of	first-level subdirectories which will be created under the Directory. The default is 16.	
.evel2	number of	second-level subdirectories which will be created under each first-level directory. The default is 256.	
Q1	number of unacknowledged I/O requests when Squid stops opening new files. If this many messages are in the queues, Squid won't open new files. Default is 64.		
Q2	number of unacknowledged messages when Squid starts blocking. If this many messages are in the queues, Squid blocks until it		

Option:

read-only Make the cache directory as read only.		
max-size=n	refers to the max object size this storedir supports. It is used to initially choose the storedir to dump the object.	

- 1. To make optimal use of the max-size limits you should order the cache_dir lines with the smallest max-size value first and the ones with no max-size specification last.
- 2. For coss, max-size must be less than COSS_MEMBUF_SZ

receives some replies. Default is 72.

Example(s)

cache_dir ufs /path/to/cache_dir 5000 16 256

Description	Defines the format for storing access logs in access.log file
Build Option	Default
Usage	logformat <name> <format specification=""></format></name>
Default	none

Using this, the default log format can be changed according to the requirement. This customizable format will be needed when you want to perform analysis on the logs stored in access.log file.

Arguments

	•		
name	Identifier holding the customized logformat		
format specification	It is a string embedded with % format codes		

% format codes all follow the same basic structure where all but the formatcode is optional. Output strings are automatically quoted as required according to their context and the output format modifiers are usually unneeded but can be specified if an explicit quoting format is desired. The logformat name should be added at the end of access log file in the access-log tag.

% ["|[|'|#] [-] [[0]width] [{argument}] formatcode

"	quoted string output format
[Squid log quoted format as used by log_mime_hdrs
#	URL quoted output format
'	No automatic quoting
-	left aligned
width	field width. If starting with 0 then output is zero padded
{arg}	argument such as header name etc

Format codos:

Format	Format codes:		
>a	Client source IP address		
>A	Client FQDN		
>p	Client source port		
<a< td=""><td>Server IP address or peer name</td></a<>	Server IP address or peer name		
la	Local IP address (http_port)		
lp	Local port number (http_port)		
ts	Seconds since epoch		
tu	subsecond time (milliseconds)		
tl	Local time. Optional strftime format argument default %d/%b/%Y:%H:%M:S %z		
tg	GMT time. Optional strftime format argument default %d/%b/%Y:%H:%M:S %z		
tr	Response time (milliseconds)		
>h	Request header. Optional header name argument on the format header[:[separator]element]		
<h< td=""><td>Reply header. Optional header name argument as for >h</td></h<>	Reply header. Optional header name argument as for >h		
un	User name		
ul	User login		
us	User SSL		
ui	User ident		
ue	User from external acl		
Hs	HTTP status code		
Ss	Squid request status (TCP_MISS etc)		
Sh	Squid hierarchy status (DEFAULT_PARENT etc)		
mt	MIME content type		
rm	Request method (GET/POST etc)		
ru	Request URL		
rv	Request protocol version		
ea	Log string returned by external acl		
<st< td=""><td>Reply size including HTTP headers</td></st<>	Reply size including HTTP headers		
>st	Request size including HTTP headers		
st	Request+Reply size including HTTP headers		
%	a literal % character		

Example(s)

logformat Squid %ts.%03tu %6tr %>a %Ss/%03Hs %<st %rm %ru %un %Sh/%<A %mt logformat combined %>a %ui %un [%tl] "%rm %ru HTTP/%rv" %Hs %<st "%{Referer}>h" "%{User-Agent}>h" %Ss:%Sh

TAG NAME	access_log [previously called as cache_access_log]
Description	Defines the file where client activities are logged
Build Option	Default
Usage	access_log <filepath> [<logformat name=""> [acl acl]]</logformat></filepath>
Default	access_log /usr/local/Squid/var/logs/access.log squid

Synopsis

All the activities the client does gets logged in this file. Using this, analysis on the access made by the clients can be done.

Customization of the logging can be done using the acl's which logs only those clauses in the specified logformat. If no acl is specified, all requests will be logged to this file.

To disable logging of a request specify "none".

Arguments

filepath	Location of the file that stores the logs
logformat name	Identifier that holds the customized log formats
acl	Filter rules to match

Example(s)

access_log /var/logs/access.log

If logformat is configured, then define the access_log as shown to get the defined logformats.

access_log /var/logs/access.log common, where common is the logformat name defined above.

<u> </u>	TAG NAME	cache_log
	Description	This tag is used to define the Cache logging file
	Build Option	Default
	Usage	cache_log <filepath>/filename</filepath>
	Default	cache store log /usr/local/Squid/yar/logs/cache log

Synopsis

This defines the path and the file where general information about your cache's behavior goes. This file contains startup configuration information, as well as assorted error information during Squid's operation. This file is a good place to look when a website is found to have problems running through the web cache. Entries here may point towards a potential solution.

Arguments

filepath	Specifies the location of the file
filename	Actual file where the log is gathered

Example(s)

cache_log /var/logs/cache.log

A	TAG NAME	cache_store_log
	Description	Configures the location of the caches store log file
	Build Option	Default
	Usage	cache_store_log <filepath>/filename</filepath>
	Default	cache_store_log /usr/local/Squid/var/logs/store.log

Synopsis

This tag defines the location where the transaction log of all objects that are stored in the object store, as well as the time when the object get deleted. This file really doesn't have very much use on a production cache, and it primarily recommended for use in debugging. Therefore, it can be turned off by entering none in the entry field.

Arguments

filepath	Specifies the location of the file
filename	Actual file where the log is gathered

Example(s)

cache_store_log /var/cache/store.log

TAG NAME	cache_swap_log
Description	Defines the filename used in each store directory to store the web caches metadata
Build Option	Default
Usage	cache_log <filepath>/filename</filepath>
Default	none

Synopsis

This tag defines the file where metadata of objects saved on disk. This is a form of index for the web cache object store. These metadata is used to rebuild the cache during startup. This is not a human readable log, and it is strongly recommended to leave it in its default location on each store directory.

If %s can be used in the file name it will be replaced with a a representation of the cache_dir name where each / is replaced with ".".

If have more than one 'cache_dir', and %s is not used in the name these swap logs will have names such as:

- 1. cache_swap_log.00
- 2. cache_swap_log.01
- 3. cache_swap_log.02

Note: You must give a full filename, not just a directory. Since this is the index for the whole object list you CANNOT periodically rotate it!

Arguments

filepath	Specifies the location of the file
filename	Actual file where the log is gathered

Example(s)

cache_swap_log /var/cache/cache_swap.log

TAG NAME	emulate_httpd_log
escription	Allows you to specify that Squid write its access.log in HTTPD common log file format
Build Option	Default
Usage	emulate_httpd_log on off
Default	emulate_httpd_log off

Synopsis

Squid write its access.log in HTTPD common log file format, such as that used by Apache and many other web servers. This allows you to parse the log and generate reports using a wider array of tools. However, this format does not provide several types of information specific to caches, and is generally less useful when tracking cache usage and solving problems. Because there are several effective tools for parsing and generating reports from the Squid standard access logs, it is usually preferable to leave this at its default of being off.

Arguments

on/off Enable or disable this proces

log_ip_on_direct Description This tag enables/disables logging of IP adress/hostname in the access.log file

log_ip_on_direct on

Build Option Default log_ip_on_direct on|off

Usage Default

Synopsis

By making this directive to on, logs the IP Address of the destination server in the access.log file. If you want the hostname to be logged, then configure the directive to off mode.

Arguments

on/off Enable or disable this process

TAG NAME	mime_table
Description	Used to define the file and path to the file where Squid's mime table is located
Build Option	Default
Usage	mime_table path/filename
Default	mime_table /usr/local/Squid/etc/mime.conf

Synopsis

Squid uses the mime table defined by this tag

Arguments

path	Path for the file where mime table file is located
filename	File that contains mime table

Example(s)

mime_table /usr/local//mime.conf

TAG NAME	log_mime_hdrs
Description	Enables to log extra information about clients requests in the access log
Build Option	Default
Usage	log_mime_hdrs on off
Default	log_mime_hdrs off

Synopsis

When enabled, causes Squid to log more information about the request in the access.log file. This causes Squid to also write the request and response MIME headers for every request. These will appear in brackets at the end of each access.log entry.

Arguments

on/off Enable or disable this process

TAG NAME	useragent_log
Description	Using this tag, you can make Squid to write User-Agent field from HTTP requests to the filename specified in this tag
Build Option	enable-useragent-log
Usage	useragent_log path/filename
Default	none

Synopsis

By default useragent_log is disabled.

Arguments

path	Path for the useragent log file
filename	File that contains useragent logs

Example(s)

useragent_log /var/logs/usragent.log

TAG NAME	referer_log
Description	Squid will write the Referer field from HTTP requests to the filename specified here
Build Option	enable-referer-log
Usage	referer_log path/filename
Default	none

Synopsis

By default referer_log is disabled.

Arguments

path	Path for the referer log file
filename	File that contains useragent logs

Example(s)

referer_log /var/logs/referer.log

TAG NAME	nid filename

Description	Used to define a filename where the process id's of Squid is stored	
Build Option	Default	
Usage	pid_filename path/filename	
Default	pid_filename /usr/local/Squid/var/logs/Squid.pid	

If you don't want Squid to create this file enter none instead of filename.

Arguments

path	Path for the Squid pid file
filename	File that contains pid of Squid's process

Example(s)

pid_filename /usr/local/Squid.pid

TAG NAME	debug_options
Description	This provides a means to configure all of Squid's various debug sections
Build Option	Default
Usage	debug_options section, level
Default	debug_options ALL,1

Synopsis

Squid's debugging code has been divided into a number of sections, so that if there is a problem in one part of Squid debug logging can be made more verbose for just that section. The magic word "ALL" sets debugging levels for all sections. We recommend normally running with "ALL,1".

Arguments

section	Defines which section's information to be logged
level	Defines debugging levels (0-9)

Example(s)

debug_options ALL, 9

TAG NAME	log_fqdn
Description	Turn this on if you wish to log fully qualified domain names in the access.log
Build Option	Default
Usage	log_fqdn on off
Default	log_fqdn off

Synopsis

This configures whether Squid will attempt to resolve the hostname, so the the fully qualified domain name can be logged. This can, in some cases, increase latency of requests.

Arguments

on/off Enable or disable this process

TAG NAME	client_netmask
Description	Defines what portion of the requesting client IP is logged in the access.log
Build Option	Default
Jsage	client_netmask netmask
Default	client_netmask 255.255.255.255

Synopsis

You can make the requesting clients IP to be logged as such or only the network part of the IP alone with the host part being zero. For privacy reasons it is often preferred to only log the network or subnet IP of the client. For example, a netmask of 255.255.255.0 will log the first three octets of the IP, and fill the last octet with a zero.

Arguments

netmask Clients network mask

Example(s)

client_netmask 255.255.120.200

OPTIONS FOR EXTERNAL SUPPORT PROGRAMS

External support programs could be viewed as a simple means of modular design, allowing third parties to write modules to improve the features of Squid. That's being said, some of Squid's standard functionality is also provided by helper programs. The standard helper programs include dnsserver, pinger, and several authentication modules. Third party modules include redirectors, and blockers, and additional authentication modules.

TAG NAME	ftp_user
Description	This is the email address Squid uses to login to remote FTP servers anonymously
Build Option	Default
Usage	ftp_user username
Default	ftp_user squid@

For login to some servers, an anonymous email address is to be used. This tag is used to provide the anonymous email address for the login. This can simply be a user name followed by an @ symbol, which your domain name can be automatically attached to. Or it can be a full email address. This should be something reasonable for your domain, such as www.user@mydomain.com, or in the domainless case first mentioned, squid@, which happens to be the default for this option.

Arguments

username User name to be used while login

Example(s)

ftp_user squid@squid.visolve.com

TAG NAME	ftp_list_width
Description	The column width for auto-generated Web pages of FTP sites queried through Squid when Squid is in forward proxy mode
Build Option	Default
Usage	ftp_list_width number
Default	ftp_list_width 32

Synopsis

This tag gives some control over how Squid formats the resulting file lists. Squid provides limited FTP proxy features to allow browsers (even older, non-FTP aware browsers) to communicate with FTP servers.

Arguments

number Column width

Example(s)

ftp_list_width 48

TAG NAME	ftp_passive
Description	If your firewall does not allow Squid to use passive connections, then turn off this option
Build Option	Default
Usage	ftp_passive on off
Default	ftp_passive on

Synopsis

Enable or disable passive connections.

Arguments

on/off Enable or disable this option

	TAG NAME	ftp_sanitycheck
Des	cription	Squid performs sanity checks of the addresses of FTP data connections ensure the data connection is to the requested server
Buil	d Option	Default
Usa	ge	ftp_sanitycheck on off
Defa	ault	ftp_sanitycheck on

Synopsis

For security and data integrity reasons Squid by default performs sanity checks of the addresses of FTP data connections ensure the data connection is to the requested server. If you need to allow FTP connections to servers using another IP address for the data connection then turn this off.

Arguments

on/off Enable or disable sanity checks

TAG NAME	ftp_telnet_protocol
Description	Allows to use the telnet protocol as transport channel for the control connection.
Build Option	Default
Usage	ftp_telnet_protocol on off
Default	ftp_telnet_protocol on

Synonsis

The FTP protocol is officially defined to use the telnet protocol as transport channel for the control connection. However, many implementations are broken and does not respect this aspect of the FTP protocol.

If there is any trouble accessing files with ASCII code 255 in the path or similar problems involving this ASCII code you can try setting this directive to off. If that helps, report to the operator of the FTP server in question that their FTP server is broken and does not follow the FTP standard.

Arguments

on/off Enable or disable telnet protocol as transport channel

	TAG NAME	check_hostnames
--	----------	-----------------

Description For security and stability reasons Squid by default checks hostnames for Internet standard RFC compliance	
Build Option	Default
Usage	check_hostnames on off
Default	check_hostnames on

If you want Squid not to perform these checks then turn this directive off.

If this directive is set to off, then squid disable the hostname validity/sanity checks before trying to look them up in DNS.

Arguments

Enable or disable hostname checks on/off

TAG NAME	allow_underscore
Description	If it is enabled, the underscore character is allowed in the Internet Hostnames
Build Option	Default
Usage	allow_underscore on off
Default	allow_underscore on

Synopsis

Underscore character is strictly not allowed in Internet hostnames but nevertheless used by many sites. Set this to off if Squid sould be strict about the standard.

Arguments

Enable or disable underscore checks in URL on/off

TAG NAME	cache_dns_program
Description	This helper program is used for DNS resolution
Build Option	disable-internal-dns
Usage	cache_dns_program program
Default	cache_dns_program /usr/local/Squid/libexec/dnsserver

Synopsis

Squid requires a non-blocking resolver for its queries, an external program called dnsserver is included in the standard distribution. This tag is used to specify the path for the external dnsserver program.

Path and the external dnsserver program program

Example(s)

cache_dns_program /usr/local/libexec/dnsserver

TAG NAME	dns_children
Description	The number of processes spawn to service DNS name lookups
Build Option	Default
Usage	dns_children number (1 to 32)
Default	dns_children 5

Specifies the number of external DNS resolver processes that will be started in order to serve requests. The default value of five is enough for many networks, however, if your Squid serves a large number of users, this value may need to be increased to avoid errors. However, increasing the number of processes also increases the load on system resources and may actually hinder performance if set too high. More than 10 is probably overkill.

Arguments

number Number of dns children program

Example(s)

dns_children 10

TAG NAME	dns_retransmit_interval	
Description	Defines the initial retransmit time interval for DNS queries	
Build Option	Default	
Usage	dns_retransmit_interval time-units	
Default	dns_retransmit_interval 5 seconds	

Synopsis

The interval is doubled each time all configured DNS servers have been tried.

Arguments

time-units Retransmit time interval

Example(s)

dns_retransmit_interval 15 seconds

TAG NAME	dns timeout

Description	This defines the DNS query timeout	
Build Option	Default	
Usage	dns_timeout time-units	
Default	dns_timeout 5 minutes	

If no response is received to a DNS query within this time then all DNS servers for the queried domain is assumed to be unavailable.

Arguments

nits DNS timeout period	time-units
-------------------------	------------

Example(s)

dns_timeout 10 minutes

	TAG NAME	dns_defnames
1	Description	Enable/disable the dnsserver to add the local domain name to single component host names
	Build Option	Default
ı	Jsage	dns_defnames on off
	Default	dns_defnames off

Synopsis

Normally the 'dnsserver' disables the RES_DEFNAMES resolver option (see res_init(3)). This prevents caches in a hierarchy from interpreting single-component hostnames locally. To allow dosserver to handle single-component names, enable this option.

Arguments

on/off	Enable or disable this option

TAG NAME	dns_nameservers	
Description	Use this if you want to specify a list of DNS name servers (IP addresses) to use	
Build Option	Default	
Usage	dns_nameservers ip_address	
Default	none	

Synopsis

Normally defaults to resolve.conf, which simply means that Squid's parent DNS servers will be drawn from the /etc/resolve.conf file found on the system Squid runs on. It is possible to select other DNS servers if needed, for example to choose a more local caching DNS server, or a remote internet connected server.

Arguments

ip	address	IP address of the dns servers

Example(s)

dns_nameservers 10.0.0.1 192.172.0.4

	TAG NAME	hosts_file	
	Description	Defines the location of the host-local IP name-address associations database	
E	Build Option	Default	
ι	Jsage	host_file path/filename	
	Default	hosts_file /etc/hosts	

Synopsis

For Unix and Linux system this file is located at /etc/hosts

Arguments

path	Path to the file that contains the ip addresses
filename	File that contains the ip addresses

Example(s)

hosts_file /hosts

TAG NAME	diskd_program	
Description	Specifies the location of the diskd executable	
Build Option	Default	
Usage	diskd_program path/filename	
Default	diskd_program /usr/local/Squid/libexec/diskd	

SynopsisThis tag is used to specify the location where diskd program is located

Note: This is only useful if you have compiled in diskd as one of the store io modules.

Arguments

path	Path where diskd program is located	
filename	File that performs diskd operation	

Example(s)

diskd_program /usr/local/libexec/diskd

TAG NAME	unlinkd_program

Description	Specifies the location where executable for file deletion process is stored
Build Option	Default
Usage	unlinkd_program path/filename
Default	unlinkd_program /usr/local/Squid/libexec/unlinkd

The name of the helper program that deletes, or unlinks old files in the cache to make room for newer objects.

Arguments

path	Path where the program is located
filename	File that performs the specified operation

Example(s)

unlinkd_program /usr/local/libexec/unlinkd

TAG NAME	pinger_program
Description	Specifies the location of the executable for the pinger process
Build Option	enable-icmp
Usage	pinger_program path/filename
Default	pinger_program /usr/local/Squid/libexec/pinger

Synopsis

An external program that provides Squid with ICMP RTT information so that it can more effectively choose between multiple remote parent caches for request fulfillment.

Arguments

path	Path of the pinger executable program
filename	File that performs the pinger process

Example(s)

pinger_program /usr/local/libexec/pinger

TAG NAME	url_rewrite_program [previously called as redirect_program]	
Description	Specifies the location of the executable for the URL redirector	
Build Option	Default	
Usage	url_rewrite_program path/to/rewriter/program	
Default	none	

Synopsis

Specify the location of the executable for the URL rewriter. Since they can perform almost any function there isn't one included.

For each requested URL, the rewriter will receive a line input with the following format URL <SP> client_ip "/" fqdn <SP> user <SP> method <SP> urlgroup <NL>

The rewriter may return a rewritten URL. The other components of the request line does not need to be returned (ignored if they are).

The rewriter can also indicate that a client-side redirect should be performed to the new URL. This is done by prefixing the returned URL with "301:" (moved permanently) or 302: (moved temporarily).

It can also return a "urlgroup" that can subsequently be matched in cache_peer_access and similar ACL driven rules. An urlgroup is returned by prefixing the returned url with "!urlgroup!"

By default, a URL rewriter is not used.

Arguments

7.1. ga	
path	Location of the rewriter program
rewriter	Executable file that performs the rewrite process

Example(s)

url_rewrite_program /usr/local/squirm/bin/squirm

TAG NAME	url_rewrite_children [previously called as redirect_children]
Description	The number of redirector processes to spawn.
Build Option	Default
Usage	url_rewrite_children number
Default	url rewrite children 5

The number of redirector processes to spawn. If you start too few Squid will have to wait for them to process a backlog of URLs, slowing it down. If you start too many they will use RAM and other system resources.

Aguments

	Ni
number	Number of rewrite process to spawn

Example(s)

url_rewrite_children 15

TAG NAME	url_rewrite_concurrency
----------	-------------------------

Description	The number of requests each redirector helper can handle in parallel.
Build Option	Default
Usage	url_rewrite_concurrency number
Default	url_rewrite_concurrency 0

The number of requests each redirector helper can handle in parallel. Defaults to 0 which indicates that the redirector is a old-style singlethreaded redirector.

Arguments

Number of requests to be handle number

Example(s)

te_concurrency 10

url	rew	rite

TAG NAME	url_rewrite_host_header [previously called as redirect_rewrites_host_header]	
Description	Enable/disable Squid rewriting any host header in redirected requests	
Build Option	Default	
Usage	url_rewrite_host_header on off	
Default	url_rewrite_host_header on	

Synopsis

By default Squid rewrites any Host: header in redirected requests.

Warning: If you are running a accelerator then this may not be a wanted effect of a redirector

Arguments

Enable /disable rewriting of host headers on/off

	TAG NAME	url_rewrite_access [previously called as redirector_access]
ı	Description	Used to define the access lists specifies which requests are sent to the redirector processes.
E	Build Option	Default
ı	Jsage	url_rewrite_access allow deny acl
	Default	none

Synopsis

Some access lists which does not need redirection can be denied using this tag. By default all requests are sent to the redirector process.

Arguments

	Allow or deny the access list
acl	List that to be allowed or denied

Example(s)

acl me src 172.16.1.35 url_rewrite_access allow me

TAG NAME	location_rewritre_program
Description	Specify the location of the executable for the Location rewriter used to rewrite server generated redirects.
Build Option	Default
Usage	location_rewrite_program path/to/program
Default	none

Synopsis

Usually used in conjunction with a url_rewrite_program.

For each Location header received the location rewriter will receive one line with the format:

location URL <SP> requested URL <SP> urlgroup <NL>

The rewriter may return a rewritten Location URL or a blank line. The other components of the request line does not need to be returned (ignored if they are).

By default, a Location rewriter is not used.

Arguments

path	Location of the rewriter program
rewriter	Executable file that performs the rewrite process

Example(s)

location_rewrite_program /usr/local/squid/loc_prog

TAG NAME	location_rewrite_children
Description	Specify the number of location rewriting processes to spawn.
Build Option	Default
Usage	location_rewrite_children number
Default	location_rewarite_children 5

The number of location rewriting processes to spawn. If you start too few Squid will have to wait for them to process a backlog of URLs, slowing it down.

If you start too many they will use RAM and other system resources.

Arguments

number Number of location rewrite process to spawn

Example(s)

location_rewrite_children 15

TAG NAME	location_rewrite_concurrency
Description	The number of requests each Location rewriter helper can handle in parallel.
Build Option	Default
Usage	location_rewrite_children number
Default location_rewrite_children 0	

Synopsis

The number of requests each Location rewriter helper can handle in parallel. Defaults to 0 which indicates that the helper is a old-style singlethreaded helper.

Arguments

number	Number of requests to be handle

Example(s)

location_rewrite_concurrency 10

TAG NAME	location_rewrite_access
Description	Used to define the access lists which are to be redirected to the location rewriting process
Build Option	Default
Usage	location_rewrite_access allow deny acl
Default	none

Some access lists specifies which requests are sent to location rewriting process. By default all requests are sent to the redirector process.

Arguments

allow/deny	Allow or deny the access list
acl	List that to be allowed or denied

Example(s)

acl me src 172.16.1.35 location_rewrite_access allow me

TAG NAME	auth_param
Description	Provides an interface to the external authentication interface within Squid
Build Option	Default
Usage	auth_param scheme parameter [setting]
Default	netdb_ping_period 5 minutes

SynopsisThis is used to pass parameters to the various authentication schemes making users to be authenticated in a number of ways. various schemes are explained below.

Scheme	Parameter	Explanation
basic	"program" cmdline	Specify the command for the external authenticator. Such a program reads a line containing "username password" and replies "OK" or "ERR" in an endless loop. If you use an authenticator, make sure you have 1 acl
		of type proxy_auth. By default, the basic authentication sheme is not used unless a program is specified.
		If you want to use the traditional proxy authentication, jump over to the/auth_modules/NCSA directory and type: % make
		% make install
		Then, set this line to something like
		auth_param basic program /usr/local/Squid/bin/ncsa_auth /usr/local/Squid/etc/passwd
	"children" numberofchildren	The number of authenticator processes to spawn (no default). If you start too few Squid will have to wait for them
		to process a backlog of usercode/password verifications, slowing it down. When password verifications are done
		via a (slow) network you are likely to need lots of authenticator processes.
		auth_param basic children 5
	"concurrency" concurrency	The number of concurrent requests the helper can process. The default of 0 is used for helpers who only supports one request at a time.
		auth_param basic concurrency 0
	"realm" realmstring	Specifies the realm name which is to be reported to the client for the basic proxy authentication scheme (part of the text the user will see when prompted their username and password). There is no default.
		auth_param basic realm Squid proxy-caching web server
	"credentialsttl" timetolive	Specifies how long Squid assumes an externally validated username:password pair is valid for - in other words how often the helper program is called for that user. Set this low to force revalidation with short lived passwords. Note that setting this high does not impact your susceptability to replay attacks unless you are using an one-time password system (such as SecureID). If you are using such a system, you will be vulnerable to replay attacks unless you also use the max.user-ip ACL in an http_access rule.

	"casesensitive" on off	Specifies if usernames are case sensitive. Most user databases are case insensitive allowing the same username to be spelled using both lower and upper case letters, but some are case sensitive.
		auth_param basic casesensitive off
	"blankpassword" on off	Specifies if blank passwords should be supported. Defaults to off as there is multiple authentication backends which handles blank passwords as "guest" access.
digest	"program" cmdline	Specify the command for the external authenticator. Such a program reads a line containing "username": "realm" and replies with the appropriate H(A1) value base64 encoded. See rfc 2616 for the definition of H(A1). If you use an authenticator, make sure you have 1 acl of type proxy_auth . By default, authentication is not used.
		If you want to use build an authenticator, jump over to the/digest_auth_modules directory and choose the authenticator to use. It's directory type % make % make install Then, set this line to something like
		auth_param digest program /usr/local/Squid/bin/digest_auth_pw /usr/local/Squid/etc/digpass
	"children" number of children	The number of authenticator processes to spawn (no default). If you start too few Squid will have to wait for them to process a backlog of H(A1) calculations, slowing it down. When the H(A1) calculations are done via a (slow) network you are likely to need lots of authenticator processes.
		auth_param digest children 5
	"realm" realmstring	Specifies the realm name which is to be reported to the client for the digest proxy authentication scheme (part of the text the user will see when prompted their username and password). There is no default.
	"nonce_garbage_interval"	auth_param digest realm Squid proxy-caching web server Specifies the interval that nonces that have been issued to client_agent's are checked for validity.
	timeinterval	Specifies the maximum length of time a given nonce will be valid for.
	nonce_max_duration timeinterval	auth_param digest nonce_max_duration 30 minutes
	"nonce_max_count" number	Specifies the maximum number of times a given nonce can be used.
		auth_param digest nonce_max_count 50
	"nonce_strictness" on off	Determines if squid requires strict increment-by-1 behavior for nonce counts, or just incrementing
	, .	auth_param digest nonce_strictness off
	"check_nonce_count" on off	This directive if set to off can disable the nonce count check completely to work around buggy digest
		qop implementations in certain mainstream browser versions.
		auth_param digest check_nonce_count on
	"post_workaround" on off	This is a workaround to certain buggy browsers who sends an incorrect request digest in POST requests when reusing the same nonce as acquired earlier in response to a GET request.
		auth_param digest post_workaround off
NTLM	"program" cmdline	Specify the command for the external ntlm authenticator. Such a program reads a line containing the undercoded NEGOTIATE and replies with the ntlm CHALLENGE, then waits for the response and answers with "OK" or "ERR" in an endless loop. If you use an ntlm authenticator, make sure you have 1 acl of type proxy_auth. By default, the ntlm authenticator_program is not used.
		auth_param ntlm program /usr/local/Squid/bin/ntlm_auth
	"children" number of children	The number of authenticator processes to spawn (no default). If you start too few Squid will have to wait for them to process a backlog of credential verifications, slowing it down. When crendential verifications are done via a (slow) network you are likely to need lots of authenticator processes.
		auth_param ntlm children 5
	"keep_alive" on off	This option enables the use of keep-alive on the initial authentication request. It has been reported some versions of MSIE have problems if this is enabled, but performance will be increased if enabled.
		auth_param ntlm keep_alive on
Negotiate	"program" cmdline	Specify the command for the external Negotiate authenticator. Such a program participates in the SPNEGO exchanges between Squid and the client and reads commands according to the Squid ntlmssp helper protocol. See helpers/ntlm_auth/
		for details. Recommended SPNEGO authenticator is ntlm_auth from Samba-4.X.
	Wate 'I down Warrant a confet. 'I down	auth_param negotiate program /path/to/samba/bin/ntlm_authhelper-protocol=gss-spnego
	"children" numberofchildren	The number of authenticator processes to spawn. If you start too few squid will have to wait for them to process a backlog of credential verifications, slowing it down.
		auth_param negotiate children 5
	"keep_alive" on off	If you experience problems with PUT/POST requests when using the Negotiate authentication scheme then you can try setting this to off.
		auth_param negotiate keep_alive on

Note: Once an authentication scheme is fully configured, it can only be shutdown by shutting Squid down and restarting.

Arguments

scheme	One of the above mentioned authentication scheme
parameter	various parameters for the schemes as listed above

Example(s)
auth_param basic program /usr/local/Squid/bin/ncsa_auth /usr/local/Squid/etc/passwd
auth_param basic children 5
auth_param basic realm Squid proxy-caching web server
auth_param basic credentialsttl 2 hours

auth_param digest program <uncomment and complete this line>

auth_param digest children 5

auth_param digest realm Squid proxy-caching web server auth_param digest nonce_garbage_interval 5 minutes

auth_param digest nonce_max_duration 30 minutes

auth_param digest nonce_max_count 50

auth_param ntlm program <uncomment and complete this line to activate>

auth_param ntlm children 5

auth_param ntlm max_challenge_reuses 0

auth_param ntlm max_challenge_lifetime 2 minutes

auth_param basic program <uncomment and complete this line to activate>

auth_param basic children 5

auth_param basic realm Squid proxy-caching web server

auth_param basic credentialsttl 2 hours

TAG NAME	authenticate_cache_garbage_interval
Description	Defines the time period between garbage collection across the username cache
Build Option	Default
Usage	authenticate_cache_garbage_interval time
Default	authenticate_cache_garbage_interval 1 hour

Synopsis

This tag is used to specify the time period between garbage collection across the username cache.

Arguments

time Specifies the time period

Example(s)

authenticate_cache_garbage_interval 2 hour

TAG NAME	authenticate_ttl
Description	Defines the time period for user & their credentials stay in the logged user cache since their last request
Build Option	Default
Usage	authenticate_ttl time
Default	authenticate_ttl 1hour

Synopsis

When the defined timeout reaches, then all user credentials that have passed their TTL are removed from memory.

Arguments

time Time period of credentials stay

Example(s)

authenticate_ttl 2 hour

TAG NAME	authenticate_ip_ttl
Description	If you use proxy authentication and the <u>max_user_ip</u> ACL, this tag controls how long Squid remembers the IP addresses associated with each user
Build Option	Default
Usage	authenticate_ip_ttl time
Default	authenticate_ip_ttl 0 seconds

Synopsis

Use a small value (e.g., 60 seconds) if your users might change addresses quickly, as is the case with dialups. You might be safe using a larger value (e.g., 2 hours) in a corporate LAN environment with relatively static address assignments.

Arguments

Time period for which the ip addresses should be remembered time

Example(s)

authenticate_ip_ttl 10 seconds

A	

TAG NAME	external_acl_type	
Description	This tag defines external acl classes using a helper program to look up the status	
Build Option	Default	
Usage	external_acl_type name [options] FORMAT path/helper [helper arguments]	
Default	none	

Synopsis

This tag defines how the external acl classes using a helper program should look up the status.

Arguments

name	External acl type name
path	Path to the external helper program
helper	Helper program

Options:

ttl=n	TTL in seconds for cached results (defaults to 3600 for 1 hour)	
negative_ttl=n	TTL for cached negative lookups (default same as ttl)	
children=n	Number of acl helper processes spawn to service external acl lookups of this type.	
concurrency=n	concurrency level per process. Use 0 for old style helpers who can only process a single request at a time.	
cache=n	result cache size, 0 is unbounded (default)	

grace=n	Percentage remaining of TTL where a refresh of a cached entry should be initiated without needing to wait for a new reply. (default 0 for no grace period)
protocol=2.5	Compatibility mode for Squid-2.5 external acl helpers

FORMAT specifications:

%LOGIN	Authenticated user login name
%IDENT	Ident user name
%SRC	Client IP
%SRCPORT	Client source port
%DST	Requested host
%PROTO	Requested protocol
%PORT	Requested port
%PATH	Requested URL path
%METHOD	Request method
%MYADDR	Squid interface address
%MYPORT	Squid http_port number
%USER_CERT	SSL User certificate in PEM format
%USER_CERTCHAIN	SSL User certificate chain in PEM format
%USER_CERT_xx	SSL User certificate attribute xx
%USER_CA_xx	SSL User certificate CA attribute xx
%{Header}	HTTP request header
%{Hdr:member}	HTTP request header list member
%{Hdr:;member}	HTTP request header list member using ; as list separator. ; can be any non-alphanumeric character.
%ACL	The ACL name
%DATA	The ACL arguments.
%DATA	The ACL arguments.

In addition, any string specified in the referencing acl will also be included in the helper request line, after the specified formats (see the "acl external" directive)

The helper receives lines per the above format specification, and returns lines starting with OK or ERR indicating the validity of the request and optionally followed by additional keywords with more details.

If protocol=3.0 (the default) then URL escaping is used to protect each value in both requests and responses.

If using protocol=2.5 then all values need to be enclosed in quotes if they may contain whitespace, or the whitespace escaped using \. And quotes or \ characters within the keyword value must be \ escaped.

When using the concurrency= option the protocol is changed by introducing a query channel tag infront of the request/response. The query channel tag is a number between 0 and concurrency-1.

General result syntax: OK/ERR keyword=value ...

Defined Keyw	Defined Keywords	
user=	ser= The users name (login)	
password=	The users password (for login= cache_peer option)	
message=	sage= Message describing the reason. Available as %o in error pages	
log=	String to be logged in access.log. Available as %ea in logformat specifications	

 $\label{thm:contain} \text{Keyword values need to be enclosed in quotes if they may contain whitespace, or the whitespace escaped using λ.}$ Any quotes or \ characters within the keyword value must be \ escaped.

Example(s)

auth_param basic program < put your authenticator here > auth_param basic children 20

auth_param basic realm Squid proxy-caching web server auth_param basic credentialsttl 1800 seconds

external_acl_type checkip children = 20 %LOGIN %SRC /usr/local/Squid/bin/checkip.pl

acl password external checkip

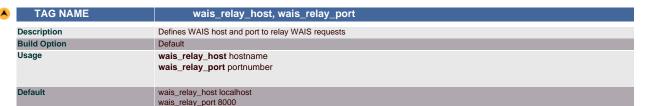

acl it src 172.16.20.1-172.16.20.199/255.255.255.255

http_access allow it password

Allows user if user belongs to a group that is allowed during a given time and using a given ip

OPTIONS FOR TUNING THE CACHE

This section describes the important parameters that determine Squid cache performance.

WAIS, or Wide Area Information System, is a system to catalog and search large amounts of data via a WAIS or WWW browser. This defaults to localhost and 8000.

Arguments

hostname	Machine name
portnumber	Port where to bind the socket

Example(s)

wais_relay_host localhost wais_relay_port 8000

TAG NAME	request_header_max_size
Description	This specifies the maximum size for HTTP headers in a request
Build Option	Default
Usage	request_header_max_size size(KB)
Default	request_header_max_size 10 KB

Synopsis

Size of HTTP headers in a request can be controlled using this tag. Request headers are usually relatively small (about 512 bytes). Placing a limit on the request header size will catch certain bugs (for example with persistent connections) and possibly buffer-overflow or denial-of-service attacks.

Arguments

size	Maximum size of request header

Example(s)

request_header_max_size 100 KB

TAG NAME	request_body_max_size
Description	Specifies the maximum size for an HTTP request body
Build Option	Default
Usage	request_body_max_size size(KB)
Default	request_body_max_size 0 KB

Synopsis

This is the maximum size of a PUT/POST request. A user who attempts to send a request with a body larger than this limit receives an "Invalid Request" error message. If you set this parameter to a zero (the default), there will be no limit imposed.

Arguments

Size Maximum size of request body	_
-----------------------------------	---

Example(s)

request_body_max_size 10 KB

TAG NAME	refresh_pattern
Description	Used to define the manner how Squid treats the objects in the cache
Build Option	Default
Usage	refresh_pattern [-i] regex min percent max [options]
Default (Suggested)	refresh_pattern ^ftp: 1440 20% 10080 refresh_pattern ^gopher: 1440 0% 1440 refresh_pattern . 0 20% 4320

Synopsis

The way how the objects in the cache be refreshed is defined using this tag. By default, regular expressions are CASE-SENSITIVE. To make them case-insensitive, use the -i option.

Basically a cached object is:

,	
FRESH	if expires < now, else STALE
STALE	if age > max
FRESH	if Im-factor < percent, else STALE
FRESH	if age < min
else	STALE

The refresh_pattern lines are checked in the order listed here. The first entry which matches is used. If none of the entries match, then the default will be used.

Arguments

, a gaine	a gamento	
regex	regular expression	
Min	time (in minutes), an object without an explicit expire time should be considered fresh.	
percent	percentage of the objects age (time since last modification age) an object without explicit expire time will be considered fresh.	
Max	upper limit on how long objects without an explicit expiry time will be considered fresh.	

Options:

override-expire	enforces min age even if the server sent a Expires: header. Doing this VIOLATES the HTTP standard. Enabling this feature could make you liable for problems which it causes.
override-lastmod	enforces min age even on objects that was modified recently.
reload-into-ims	changes client no-cache or ``reload" to If-Modified-Since requests. Doing this VIOLATES the HTTP standard. Enabling this feature could make you liable for problems which it causes.
ignore-reload	ignores a client no-cache or ``reload" header. Doing this VIOLATES the HTTP standard. Enabling this feature could make you liable for problems which it causes.
ignore-no-cache	ignores any ``Pragma: no-cache" and ``Cache-control: no-cache" headers received from a server.
ignore-private	ignores any ``Cache-control: private" headers received from a server. Doing this VIOLATES the HTTP standard. Enabling this feature could make you liable for problems which it causes.

ignore-auth	caches responses to requests with authorization, irrespective of ``Cache-control" headers received from a
	server. Doing this VIOLATES the HTTP standard. Enabling this feature could make you liable for problems which it
	causes.

Example(s)

refresh_pattern ^ftp: 1440 20% 10080 refresh_pattern ^gopher: 1440 0% refresh_pattern . 0 20% 4320

TAG NAME	quick_abort_min, quick_abort_max, quick_abort_pct
Description	Signals the cache how to continue downloads during abort signals sent by the clients
Buid Option	Default
Usage	<pre>quick_abort_min size quick_abort_max size quick_abort_pct percent</pre>
Default	quick_abort_min 16 KB quick_abort_max 16 KB quick_abort_pct 95

Synopsis

The cache by default continues downloading aborted requests which are almost completed (less than 16 KB remaining). This may be undesirable on slow (e.g. SLIP) links and/or very busy caches. Impatient users may tie up file descriptors and bandwidth by repeatedly requesting and immediately aborting downloads.

Arguments

size	Minimum and maximum transfer size
percent	Percentage of transfer

When the user aborts a request, Squid will check the quick_abort values to the amount of data transferred until then.

If the transfer has less than <code>quick_abort_min</code> KB remaining, it will finish the retrieval.

If the transfer has more than <code>quick_abort_max</code> KB remaining, it will abort the retrieval.

If more than quick_abort_pct of the transfer has completed, it will finish the retrieval.

If you do not want any retrieval to continue after the client has aborted, set both quick_abort_min and quick_abort_max to '0 KB'.

If you want retrievals to always continue if they are being cached then set quick_abort_min to '-1 KB'.

Example(s)

quick_abort_min 30 KB

quick_	_aboit_	_IIIax o	JIND
quick_	_abort_	_pct 80	

	TAG NAME	read_ahead_gap
D	escription	Define the amount of data the cache will buffer ahead of what has been sent to the client when retrieving an object from another server
В	uid Option	Default
U	sage	read_ahead_gap buffer-size
D	efault	read_ahead_gap 17 KB

Synopsis

This tag determines the prefetch cache buffer size for holding objects from another server while sending to the client.

Arguments

buffer-size Size of the cache buffer

Example(s)

read_ahead_gap 30 KB

TAG NAME	negative_ttl
Description	Defines Time-to-Live (TTL) for failed requests
Buid Option	Default
Usage	negative_ttl time-units
Default	negative_ttl 5 minutes

Certain types of failures (such as "connection refused" and "404 Not Found") are negatively-cached for a configurable amount of time. The default is 5 minutes. Note that this is different from negative caching of DNS lookups.

Arguments

time-units Timeout for negatively cached objects

Example(s)

negative_ttl 1 minutes

•	

TAG NAME	positive_dns_ttl
Description	Defines Time-to-Live (TTL) for positive caching of successful DNS lookups
Buid Option	Default
Usage	positive_dns_ttl time-units
Default	positive_dns_ttl 6 hours

For positive caching of successful DNS lookups, this defines Time-to-Live period. Default is 6 hours (360 minutes). If you want to minimize the use of Squid's ipcache, set this to 1, not 0.

Arguments

time-units	Timeout for positive cachings

Example(s)

positive_dns_ttl 24 hours

TAG NAME	negative_dns_ttl
Description	Time-to-Live (TTL) for negative caching of failed DNS lookups
Buid Option	Default
Usage	negative_dns_ttl time-units
Default	negative_dns_ttl 1 minutes

Synopsis

Sometimes DNS lookups may get failed. This parameter defines the Time-To-Live period for failed DNS lookups. Normally this will be a small value.

Arguments

time-units Timeout period

Example(s)

negative_dns_ttl 1 minutes

TAG NAME	range_offset_limit
Description	Sets a upper limit on how far into the file a Range request may be to cause Squid to prefetch the whole file
Buid Option	Default
Usage	range_offset_limit bytes
Default	range_offset_limit 0 KB

Synopsis

If beyond this limit then Squid forwards the Range request as it is and the result is NOT cached.

This is to stop a far ahead range request (lets say start at 17MB) from making Squid fetch the whole object up to that point before sending anything to the client.

A value of -1 causes Squid to always fetch the object from the beginning so that it may cache the result. (2.0 style) A value of 0 causes Squid to never fetch more than the client requested. (default)

Arguments

Upper limit for the range request bytes

Example(s)

range_offset_limit 17 MB

TAG NAME	collapsed_forwarding
Description	Enables multiple requests for the same URI to be processed as one request.
Buid Option	Default
Usage	collapsed_forwarding on off
Default	collapsed_forwarding off

Synopsis

This option enables multiple requests for the same URI to be processed as one request. Normally disabled to avoid increased latency on dynamic content, but there can be benefit from enabling this in accelerator setups where the web servers are the bottleneck and reliable and returns mostly cacheable information.

Arguments

on/off Enable or disable this process

TAG NAME	refresh_stale_hit
Description	Changes the refresh algorithm to allow concurrent requests while an object is being refreshed to be processed.
Buid Option	Default
Usage	collapsed_forwarding on off
Default	collapsed_forwarding off

This option changes the refresh algorithm to allow concurrent requests while an object is being refreshed to be processed as cache hits if the object expired less than X seconds ago.

Default is 0 to disable this feature. This option is mostly interesting in accelerator setups where a few objects is accessed very frequently.

Arguments

time-units	Timeout for refresh
time-units	Timeout for refresh

TIMEOUT

Timeout parameters in Squid can be based on overall connection timeouts, peer-specific timeouts, site/domain-specific timeouts, request-specific timeouts etc. Proper setting of timeout values is critical to optimal Squid performance. Relevant parameters for timeout settings are listed here.

TAG NAME	forward_timeout
Description	Specifies how long Squid should at most attempt in finding a forwarding path for the request before giving up.
Build Option	Default
Usage	forward_timeout time-units
Default	forward_timeout 4 minutes

Synopsis

This parameter specifies how long Squid should at most attempt in finding a forwarding path for the request before giving up.

Arguments

time-units Connection timeout period

Example(s)

forward_timeout 4 minutes

TAG NAME	connect_timeout
Description	An option to force Squid to close connections after a specified time
Build Option	Default
Usage	connect_time-units
Default	connect_timeout 2 minutes

Synopsis

Some systems (notably older Linux versions) can not be relied upon to time out connect requests. For this reason, this option specifies the timeout for how long Squid should wait for the connection to complete. This value defaults to 120 seconds (2 minutes).

Arguments

time-units Connection timeout period

Example(s)

connect_timeout 180 seconds

TAG NAME	peer_connect_timeout
Description	This parameter specifies how long to wait for a pending TCP connection to a peer cache
Build Option	Default
Usage	peer_connect_timeout time-units
Default	peer_connect_timeout 30 seconds

Synopsis

default is 30 seconds. You may also set different timeout values for individual neighbors with the 'connect-timeout' option on a cache_peer line.

Note: Setting of peer_connect_timeout to more than 30 seconds will be a performance issue.

Arguments

time-units Time to wait for pending TCP connection

Example(s)

peer_connect_timeout 45 seconds

TAG NAME	read_timeout
Description	Used to set the timeout period for server-side connections
Build Option	Default
Usage	read_timeout time-units
Default	read_timeout 15 minutes

On each successful read() request the timeout is reset to this amount. If no data is read within this period of time, the request is aborted and logged with ERR_READ_TIMEOUT.

Arguments

time-units Reset time duration

Example(s) read_timeout 10 minutes

TAG NAME	request_timeout	
----------	-----------------	--

Description	Defines the timeout for HTTP requests from clients	
Build Option	Default	
Usage	request_time-units	
Default	request_timeout 5 minutes	

Using this, instruct Squid to wait for an HTTP request after initial connection establishment. By default the value is 5 minutes.

Arguments

time-units	Wait time period after initial connection establishment
ume-units	wait time period after initial connection establishment

Example(s)

request_timeout 8 minutes

ıeq	lues	·L_

TAG NAME	persistent_request_timeout
Description	This defines the time period to wait for the next HTTP request on a persistent connection after the previous request completes
Build Option	Default
Usage	persistent_request_timeout time-units
Default	persistent_request_timeout 1 minute

Synopsis

This tag defines the time period between completion of a HTTP request and starting of the next request on persistent connection.

Arguments

time-units Time duration between the requests

Example(s)

persistent_request_timeout 1 minute

TAG NAME	client_lifetime
Description	The time limit Squid sets for a client to remain connected to the cache process
Build Option	Default
Usage	client_lifetime time-units
Default	client_lifetime 1 day

Synopsis

This defines the maximum amount of time that a client (browser) is allowed to remain connected to the cache process. This is merely a safeguard against clients that disappear without properly shutting down. It is designed to prevent a large number of sockets from being tied up in a CLOSE_WAIT state. The default for this option is 1440 minutes, or 1 day.

Note

The default value is intended to be much larger than any client would ever need to be connected to your cache. You should probably change client_lifetime only as a last resort. If you seem to have many client connections tying up file descriptors, we recommend first tuning the <u>read_timeout</u>, <u>request_timeout</u>, <u>pconn_timeout</u> and quick_abort values. If the more file descriptors are in use then the memory in use will also increase, which is also a performance issue.

Arguments

time-units Client lifetime with the cache

Example(s)

client_lifetime 1000 minutes

TAG NAME	half_closed_clients
Description	Defines Squid's behavior towards some types of clients that close the sending side of a connection while leaving the receiving side open
Build Option	Default
Usage	half_closed_clients on/off
Default	half_closed_clients on

Synopsis

Turning this option off will cause Squid to immediately close connections when a read(2) returns "no more data to read". It's usually safe to leave this at the default value of on.

Arguments

on/off Enable or disable this action

Example(s)

half_closed_clients off

TAG NAME	pconn_timeout
Description	Defines the timeout value for persistent connections
Build Option	Default
Usage	pconn_timeout time-units
Default	pconn timeout 120 seconds

Synopsis

When this timeout is set, Squid will close persistent connections if they are idle for this amount of time. Persistent connections will be disabled entirely if this option is set to a value less than 10 seconds. The default is 120 seconds.

Arguments

time-units Time period to wait for closing idle connections

Example(s)

pconn_timeout 2 minutes

I AG NAME	ident_timeout
Description	Maximum time to wait for IDENT lookups to complete
Build Option	Default
Usage	ident_timeout time-units
Default	ident_timeout 10 seconds

The timeout, usually in seconds. If this is set too high, you may be susceptible to denial or service from having too many outstanding ident requests. The default for this is 10 seconds.

Arguments

-units Time duration to wait during ident lookups	
---	--

Example(s)

ident_timeout 5 seconds

TAG NAME	shutdown_lifetime
Description	This is the time Squid allows for existing connections to continue after it has received a shutdown signal
Build Option	Default
Usage	shutdown_lifetime time-units
Default	shutdown_lifetime 30 seconds

Synopsis

When SIGTERM or SIGHUP is received, the cache is put into "shutdown pending" mode until all active sockets are closed. It will stop accepting new connections immediately, but connections already in progress will continue to be served for this amount of time. Defaults to 30 seconds, which is a good safe value. Any active clients after this many seconds will receive a "timeout" message.

Note

If this time is set to be too low then some file descriptors may remain open which will be a performance issue in memory usage.

Arguments

time-units Time period of "shutdown pending" mode

Example(s)

shutdown_lifetime 20 seconds

ACCESS CONTROLS

Access control settings are among the most important features of Squid. You can configure Squid to set filters for various entities and at different granularities (e.g. filters for specific protocols, filters for certain types of commands, filters for specific routers, filters for specified domains, etc).

TAG NAME	acl
Description	Used to define an Access List
Build Option	Default
Usage	acl aclname acltype string1 acl aclname acltype "file"
Default	Required minimum configuration for normal functioning

Synopsis

The first field represents the name of the ACL, which is simply an assigned name, that can be just about anything the user chooses. The second field is the type of the ACL, which can be one of a number of choices, that indicates to Squid what part of a request should be matched against for this ACL. The possible types include the requesting clients address, the Web server adquests or host name, a regular expression matching the URL, and many more. The final field is the actual string to match. Depending on what the ACL type is, this may be an IP address, a series of IP addresses, a URL, a host name, etc.

When using "file", the file should contain one item per line.

Arguments

aclname	Name of the acl
acltype	Type of acl
string	String to match
file	File that containing strings

ACL TYPE	src
Description	The IP address of the requesting client, or the clients IP Address
Build Option	Default
Usage	acl aclname src ip-address/netmask (clients IP address) acl aclname src addr1-addr2/netmask (range of addresses)

Synopsis

Matching done based on clients ip address

Arguments

aclname	Access list name
ip-address	Clients ip address
netmask	Network mask
add1-addr2	Range of ip address

Example(s)

acl network1 src 172.16.1.0/24 - refers to the whole Network with address 172.16.1.0
acl source1 src 172.16.1.25/32 - refers to a single source
acl srcrange src 172.16.1.25-172.16.1.35/32 - refers range of IP Addresses from 172.16.1.25-172.16.1.35

Description	Same as src but looks for destination IP Address	
Build Option	Default	
Usage	acl adname dst ip-address/netmask (URL host's IP address)	

First Squid will dns-lookup for IPAddress from the domain-name, which is in request header. Then this acl is interpreted.

Arguments

aclname	Access list name	
ip-address	ip-address of the oirgin server/machine	
netmask	Network mask	

Example(s)

acl dest dst 63.194.81.67/32

A	ACL TYPE	myip
	Description	The local IP address on which the client connection exists.
	Build Option	Default
	Usage	acl aclname myip ip-address/netmask (local socket IP address)

Synopsis

Using this acl type, we can specify the local IP address on which the clients connections exists. This allows ACLs to be constructed that only match one physical network, if multiple interfaces are present on the proxy, among other things.

Arguments

aclname	Access list name
ip-address	ip address of the local machine
netmask	Network mask

Example(s)

acl myip1 myip 172.16.1.53/32

ACL TYPE	arp
Description	Ethernet (MAC) address matching
Build Option	enable-arp-acl
Usage	acl aclname arp mac-address

Synopsis

This option only works for clients on the same local subnet, and only for certain platforms. Linux, Solaris, and some BSD variants are the supported operating systems for this type of ACL. This ACL can provide a somewhat secure method of access control, because MAC addresses are usually harder to spoof than IP addresses, and you can guarantee that your clients are on the local network (otherwise no ARP resolution can take place).

Arguments

aclname	Access list name
mac-address	Physical address to be matched

Example(s)

acl ACLARP arp 11:12:13:14:15:16

ACLARP refers MACADDRESS of the ethernet 11:12:13:14:15:16

Default

Note

Squid can only determine the MAC address for clients that are on the same subnet. If the client is on a different subnet, then Squid cannot find out its MAC address.

acl aclname srcdomain .domain-name .

A	ACL TYPE	srcdomain
	Description	This acl type provides matches against the client domain name

Synopsis

Usage

Build Option

Matching can be either a single domain name, or a list or domain names, or the path to a file that contains a list of domain names. If a path to a file, it must be surrounded by parentheses. This ACL type can increase the latency, and decrease throughput significantly on a loaded cache, as it must perform an address-to-name lookup for each request, so it is usually preferable to use the Client IP Address type.

Note: Here "." is more important.

Arguments

aclname	Access list name
domain-name	Clients domain name

Example(s)

acl mydomain srcdomain .kovaiteam.com

ACL TYPE dstdomai

Description	This refers to destination domain i.e. the source domain where the origin server is located
Build Option	Default
Usage	acl aclname dstdomain .domain-name

When matching to be done based on the destination servers domain, you can use this acl type.

Note: Here "." is more important.

Arguments

aclname	Access list name
domain-name	Destination domain

Example(s)

acl domain1 dstdomain .kovaiteam.com This looks for *.kovaiteam.com from URL

ACL TYPE	srcdom_regex
Description	Matches against the client domain name
Build Option	Default
Usage	acl aclname srcdom_regex [-i] pattern

Synopsis

Matching can be either a single domain name, or a list of domain names, or a path to a file that contains a list of domain names. If a path to a file ia specified, it must be surrounded parentheses.

Arguments

aclname	Access list name
pattern	Pattern to match

Example(s)

acl aclname srcdom_regex kovai - This looks for the word kovai from the client domain name

ACL TYPE	dstdom_regex
Description	Provides match against destination domain
Build Option	Default
Usage	acl aclname dstdom_regex [-i] pattern

Synopsis

Matching done on destination domain based on regular expression.

Arguments

aclname	Access list name
pattern	Patern to match

Example(s)

acl domain1 dstdom_regex redhat - This looks for the word redhat from the client's regest.

ACL TYPE	time
Description	This type is just what it sounds like, providing a means to create ACLs that are active during certain times of the day or certain days of the week
Build Option	Default
Usage	acl aclname time [day-abbrevs] [h1:m1-h2:m2]

Synopsis

Provides timed filter settings. This feature is often used to block some types of content or some sections of the internet during business or class hours. Many companies block pornography, entertainment, sports, and other clearly non-work related sites during business hours, but then unblock them after hours. This might improve workplace efficiency in some situations (or it might just offend the employees). This ACL type allows you to enter days of the week and a time range, or select all hours of the selected days.

Day-abbrevs:	
S	Sunday
М	Monday
Т	Tuesday
W	Wednesday
Н	Thursday
F	Friday
Α	Saturday
Time:	
h1:m1 must be less than h2:m2	

Arguments

aclname	Access list name
day-abbrevs	Days list (as shown above)
h1:m1-h2:m2	from and to time

acl acltime time M 9:00-17:00 - acltime refers day of Monday and time from 9:00 to 17:00.

Description	Matches using a regular expression on the complete URL
Build Option	Default
Usage	acl adname url regex [-i] pattern

This ACL can be used to provide access control based on parts of the URL or a case insensitive match of the URL, and much more. The regular expressions used in Squid are provided by the GNU Regex library which is documented in the section 7 and 3 regex manpages. Regular expressions are also discussed briefly in a nice article by Guido Socher at LinuxFocus.

Arguments

aclname	Access list name
pattern	Matching to be done for

Example(s)

acl reject url_regex -i ^http://www.google.co.in/index.html

reject contains the entire url http://www.google.co.in/index.html. If in the http://www.google.co.in/index.html. If in the http://www.google.co.in/index.html but allows the url <a href="http://www.

ACL TYPE	urlpath_regex
Description	This ACL matches on the URL path minus any protocol, port, and host name information
Build Option	Default
Usage	acl aclname urlpath_regex [-i] pattern

Synopsis

This acl type expects for the particular pattern alone from the given URLs. If found the words, it will match it.

Arguments

aclname	Access list name
pattern	Pattern which is expected for match

Example(s)

acl reject url_regex -i index.html

reject contains the pattern index.html. If in the http_access if you deny reject, then for any url containing the pattern index.html will be denied.

ACL TYPE	urllogin
Description	The ACL regular expression matching on URL login field
Build Option	Default
Usage	acl aclname urllogin [-i] [^a-zA-Z0-9]

Synopsis

Regular Expression matching on URL login field

Arguments

aclname	Access list name
pattern	Pattern which ia expected for match

Example(s)

acl urllogin -i adminstrator

ACL TYPE	port	
Description	This ACL matches on the destination port for the request	
Build Option	Default	
Usage	acl aclname port port-number acl aclname port range	

Synopsis

Matching done on the destination port.

Arguments

ga		
aclname	Access list name	
port-number	Destination port number	
range	Range of port numbers	

Example(s)

The following allows access only to the destination 172.16.1.115:80 from network 172.16.1.0

acl acceleratedhost dst 172.16.1.115/255.255.255.255

acl acceleratedport port 80

acl mynet src 172.16.1.0/255.255.255.0

http_access allow acceleratedhost acceleratedport mynet

http_access deny all

ACL TYPE

myport

Description	This provides match against local socket TCP port	
Build Option	Default	
Usage	acl aclname myport port-numbers	

Matching done on local interface port.

Arguments

aclname	Access list name
port-numbers	Local interface port numbers

Example(s)

acl mp myport 3128 http_access deny 3128

http_access allow all

These will deny all requests coming to the port 3128. Allows requests coming at all other ports.

ACL TYPE	proto	
Description	This ACL matches on the protocol of the request	
Build Option	Default	
Usage	acl aclname proto protocol	

Synopsis

Matching done based on protocol used in the request such as FTP, HTTP, ICP, etc.

Arguments

aclname	Access list name
protocol	Protocol to be matched

Example(s)

acl myproto proto HTTP FTP - This refer protocols HTTP and FTP

ACL TYPE	method
Description	This ACL type matches the HTTP method in the request headers. This includes the methods GET, PUT, etc
Build Option	Default
Usage	acl aclname method method-type

Synopsis

Matching done based on the HTTP request method like GET, PUT, etc.

Arguments

aclname	Access list name
method-type	HTTP request method

Example(s)

acl getmethod method GET POST - This refers get and post methods only.

ACL TYPE	browser
Description	A regular expression that matches the clients browser type based on the user agent header
Build Option	Default
Usage	acl aclname browser [-i] regexp

Synopsis
This allows for ACL's to operate based on the browser type in use, for example, using this ACL type, one could create an ACL for Netscape users and another for Internet Explorer users.

Arguments

gainente	
aclname	Access list name
regexp	Browser name

Example(s)

acl aclname browser MOZILLA

This refers to the requests, which are coming from the browsers who have "MOZILLA" keyword in the user-agent header.

ACL TYPE	referer_regex
Description	Pattern match on Referer header
Build Option	Default
Usage	acl aclname referer_regex [-i] pattern

Synopsis

Pattern match on Referer header

Note: Referer is highly unreliable, so use with care

Arguments

aclname	Access list name
pattern	Pattern to be matched

Example(s)

In your Squid.conf configuration file you would write something like this,

acl expression referer_regex -i user1

This looks for the pattern "user1" in username

Description	Provides string matching on user name
Build Option	Default
Usage	acl aclname ident username

Matching based on iden lookups.

Note: Need an external ident server server running on the client machines.

Arguments

aclname	Access list name
username	Username to be matched

Example(s)

You can use ident to allow specific users access to your cache. In your Squid.conf configuration file you would write something like this, ident_lookup_access allow all acl friends ident kim lisa frank joe http_access allow friends

http_access deny all

ACL TYPE	ident_regex
Description	Provides string match on ident output
Build Option	Default
Usage	acl aclname ident_regex [-i] pattern

Synopsis

Same as ident but matching is done on ident output.

Note: Need an external ident server server running on the client machines.

Arguments

aclname	Access list name
pattern	Pattern to be matched

Example(s)

In your Squid.conf configuration file you would write something like this,

ident_lookup-access allow all

acl friends ident_regex joe

This looks for the pattern "joe" in username

ACL TYPE	src_as, dst_as
Description	Source Autonomous System Number is another AS related ACL type, and matches on the AS number of thesource of the request Destination Autonomous System Number is the AS number of the server being queried
Build Option	Default
Usage	acl adname src_as number

Synopsis

The autonomous system number ACL types are generally only used in Cache Peer, or ICP, access restrictions. Autonomous system numbers are used in organizations that have multiple internet links and routers operating under a single administrative authority using the same *gateway protocol*. Routing decisions are then based on knowledge of the AS in addition to other possible data.

Arguments

aclname	Access list name
number	AS numbers to be matched

Example(s)

An example for routing all requests for AS#1241 and only those to mycache.mydomain.net

acl asexample dst_as 1241

cache_peer_access mycache.mydomain.net allow asexample

cache_peer_access mycache_mydomain.net deny all

ACL TYPE	proxy_auth
Description	This ACL type calls an external authenticator process to decide whether the request will be allowed
Build Option	Default
Usage	acl aclname proxy_auth [-i] username

Synopsis

Some of the authenticator helper programs available for Squid are PAM, NCSA, UNIX passwd, SMB, NTLM, etc. Note that authentication cannot work on a transparent proxy or HTTP accelerator. The HTTP protocol does not provide for two authentication stages (one local and one on remote Web sites). So in order to use an authenticator, your proxy must operate as a traditional proxy, where a client will respond appropriately to a proxy authentication request as well as external Web server authentication requests.

Note: proxy_auth can't be used in a transparent proxy. It collides with any authentication done by origin servers. It may seem like it works at first, but it doesn't. When a Proxy-Authentication header is sent but it is not needed during ACL checking the username is NOT logged in access.log.

Arguments

aclname	Access list name
username	User name to be authenticated

Example(s)

acl ACLAUTH proxy_auth ramesh senthil muthu

http_access allow ACLAUTH

http_access deny all

The above configuration will allow only ramesh, senthil and muthu if they give valid username and password.

Description	As above, this ACL calls an external authenticator process, but allows regex pattern or case insensitive matches	
Build Option	Default	
Usage	acl aclname proxy_auth_regex [-i] pattern	

Matching based on regular expressions using external authentication process.

Arguments

aclname	Access list name
pattern	Pattern to be matched

Example(s)

UTH proxy_auth_regex -i mesh

ac	AC	LA

ACL TYPE	snmp_community string	
Description	Provides matching against community string to limit access to your SNMP Agent	
Build Option	Default	
Usage	acl aclname snmp_community string	

Synopsis

Matching done on snmp community strings.

Arguments

aclname	Access list name
string	String to be matched

Example(s)

acl snmppublic snmp_community public

ACL TYPE	maxconn	
Description	Matches when the client's IP address has more than the specified number of HTTP connections established	
Build Option	Default	
Usage	acl aclname maxconn number	

Synopsis

Matching is true when the defined number of HTTP connections has been established for a client.

Arguments

aclname	Access list name
number	Maximum number of HTTP connections

Example(s)

acl someuser src 1.2.3.4

acl twoconn maxconn 5

http_access deny someuser twoconn

http_access allow !twoconn

The above configuration will allow a maximum of 5 http connection to access.

ACL TYPE	max_user_ip
Description	This will be matched when the same user attempts to log in for more than the specified number of times from different ip addresses
Build Option	Default
Usage	acl aclname max_user_ip [-s] number

If -s is specified then the limit is strict, denying browsing from any further IP addresses until the ttl has expired. Without -s Squid will just annoy the user by "randomly" denying requests. (the counter is then reset each time the limit is reached and a request is denied). The <u>authenticate_ip_ttl</u> parameter controls the timeout on the ip entries.

- 1. Any authentication program must be running for this. NCSA will a simple configuration.
- 2. In acceleration mode or where there is mesh of child proxies, clients may appear to come from multiple addresses if they are going through proxy farms, so a limit of 1 may cause user problems.

Arguments

aclname	Access list name
number	Number of times to login

Example(s)

authenticate_ip_ttl 2 hours acl maxuser max_user_ip -s 2 http_access deny maxuser

The same user can log to a maximum of 2 times from two different machines and when he tries to login for the third time from a third system, he will not be allowed to browse.

Description	Match against the mime type of the request generated by the client
Build Option	Default
Usage	acl aclname req mime type mime type

Using this you can detect file upload or some types HTTP tunneling requests.

Arguments

aclname	Access list name
mime_type	Mime type at the requesting side

Example(s)

acl mymime req_mime_type text
This acl looks for the pattern "text" in request mime header.

This does NOT match the reply. You cannot use this to match the returned file type.

A	ACL TYPE	req_header
	Description	Match against any of the known request headers.
	Build Option	Default
	Usage	acl aclname req_header header-name [-i] regular Expression

Synopsis

Regular Expression match against any of the known request headers.

May be thought of as a superset of "browser", "referer" and "mime-type" ACLs.

Arguments

1	Access list name
header-name	Name at the requesting side

Example(s)

acl myheader req_header text
This acl looks for the pattern "text" in request header.

ACL TYPE	rep_mime_type
Description	Match against the mime type of the reply received by Squid
Build Option	Default
Usage	acl aclname rep_mime_type mime_type

Synopsis

Also, using this, you can detect file download or some types HTTP tunneling requests.

This has no effect in http-access rules. It only has effect in rules that affect the reply data stream such as http-reply-access.

Arguments

aclname	Access list name
mime_type	Mime type at the receiving side

Example(s)

acl m2 rep_mime_type ^application/pdf\$

http_reply_access deny m2
This blocks access to application/pdf mime types.

ACL TYPE	rep_header
Description	Match against any of the known response headers.
Build Option	Default
Usage	acl aclname rep_header header-name [-i] regular expression

Synopsis

Regular Expression match against any of the known response headers.

Arguments

aclname	Access list name
header-name	Header name at the receiving side

Example(s)

acl many_spaces rep_header Content-Disposition -i [[:space:]]{3,}

ACL TYPE	external
Description	Provides match against external ACL lookup via a helper class defined by the external_acl_type tag
Build Option	Default
Usage	acl aclname external class_name [arguments]

Provides match against external ACL lookup via a helper class defined by the external acl type tag

Arguments

aclname	Access list name	
class_name	Defined by external_acl_type tag	

Example(s)

auth_param basic program < put your authenticator here > auth_param basic children 20 auth_param basic realm Squid proxy-caching web server auth_param basic credentialsttl 1800 seconds

external_acl_type checkip children=20 %LOGIN %SRC /usr/local/Squid/bin/checkip.pl

acl password external checkip acl it src 172.16.20.1-172.16.20.199/255.255.255.255

http_access allow it password

Allows user if user belongs to a group that is allowed during a given time and using a given ip.

A	ACL TYPE	urlgroup
	Description	This will match against the urlgroup as indicated by redirectors.
	Build Option	Default
	Lleane	acl adnama urlaroup group1

Synopsis

match against the urlgroup as indicated by redirectors

Arguments

aclname	Access list name
group Set of url's indicated by redirectors	

Example(s)

acl jobs urlgroup job http_access deny jobs

A	ACL TYPE	user_cert
	Description	This will match against the attributes in a user SSL certificate
	Build Option	Default
	Usage	acl aclname user_cert attribute values

Synopsis

Match against attributes in a user SSL certificate

Arguments

aclname	Access list name
attribute	Any one of DN/C/O/CN/L/ST

ACL TYPE	ca_cert
Description	This will match against attributes a users issuing CA SSL certificate
Build Option	Default
Usage	acl aclname ca cert attribute values

Synopsis

Match against attributes in a user CA SSL certificate

Arguments

	aclname	Access list name
	attribute	Any one of DN/C/O/CN/L/ST

ACL TYPE	ext_user,extuser_regex
Description	String match on username returned by external acl
Build Option	Default
Usage	acl aclname ext_user username
	acl adname ext_user_regex [-i] pattern

SynopsisString match on username returned by external acl Use REQUIRED to accept any user name.

Arguments

aclname	Access list name
username	Username for match the external user
pattern	regular Expression pattern to match External user

acl all src 0.0.0.0/0.0.0.0
acl manager proto cache_object
acl localhost src 127.0.0.1/255.255.255.255
acl to_localhost dst 127.0.0.0/8
acl SSL_ports port 443 563
acl Safe_ports port 80
acl Safe_ports port 21
acl Safe_ports port 21
acl Safe_ports port 70
acl Safe_ports port 1025-65535
acl Safe_ports port 20
acl Safe_ports port 20
acl Safe_ports port 20
acl Safe_ports port 20
acl Safe_ports port 1025-65535
acl Safe_ports port 488
acl Safe_ports port 591
acl Safe_ports port 591
acl Safe_ports port 591
acl Safe_ports port 591

acl CONNECT method CONNECT

TAG NAME	follow_x_forwarded_for
Description	Allowing or Denying the X-Forwarded-For header to be followed to find the original source of a request.
Build Option	Default
Usage	follow_x_forwearded_for allow deny [!] aclname
Default	follow_x_forwarded_for deny all

Synopsis

Requests may pass through a chain of several other proxies before reaching this proxy. The X-Forwarded-For header will contain a comma-separated list of the IP addresses in the chain, with the rightmost address being the most recent.

If a request reaches us from a source that is allowed by this configuration item, then we consult the X-Forwarded-For header to see where that host received the request from.

If the X-Forwarded-For header contains multiple addresses, and if acl_uses_indirect_client is on, then we continue backtracking until we reach an address for which we are not allowed to follow the X-Forwarded-For header, or until we reach the first address in the list

The end result of this process is an IP address that we will refer to as the indirect client address. This address may be treated as the client address for access control, delay pools and logging, depending on the acl_uses_indirect_client, delay_pool_uses_indirect_client and log_uses_indirect_client options.

Note

SECURITY CONSIDERATIONS:

Any host for which we follow the X-Forwarded-For header can place incorrect information in the header, and Squid will use the incorrect information as if it were the source address of the request. This may enable remote hosts to bypass any access control restrictions that are based on the client's source addresses.

Arguments

allow/deny	Allow or deny on matching the acl
aclname	Access list to be allowed/denied on match

Example(s)

acl localhost src 127.0.0.1
acl my_other_proxy srcdomain .proxy.example.com
follow_x_forwarded_for allow localhost
follow_x_forwarded_for allow my_other_proxy

TAG NAME	acl_uses_indirect_client			
Description	Controls whether the indirect client address is used instead of the direct client address in acl matching.			
Build Option	Default			
Usage	acl_uses_indirect_client on off			
Default	acl_uses_indirect_client on			

Synopsis

Controls whether the indirect client address (refer follow x forwarded for) is used instead of the direct client address in acl matching.

Arguments

on/off Enable/Disable the acl indirect client feature

Example(s)

acl_uses_indirect_client off

TAG NAME	delay_pools_uses_indirect_client			
Description	Controls whether the indirect client address is used instead of the direct client address in delay pools.			
Build Option	Default			
Usage	delay_pools_uses_indirect_client on off			
Default	delay_pool_uses_indirect_client on			

Synopsis

Controls whether the indirect client address (Refer follow x forwarded for) is used instead of the direct client address in delay pools.

Arguments

on/off Enable/Disable the delay pools indirect client feature

Example(s)

delay_pool_uses_indirect_client off

Description	Controls whether the indirect client address is used instead of the direct client address in the access log.				
Build Option	Default				
Usage	log_uses_indirect_client on off				
Default	log_uses_indirect_client on				

Controls whether the indirect client address (Refer follow x forwarded for) is used instead of thedirect client address in the access log.

Arguments

on/off Enable/Disable the delay pools indirect client feature

Example(s)

log_uses_indirect_client off

TAG NAME	http_access
Description	Using this, you can allow or deny the access lists defined by acl
Build Option	Default
Usage	http_access allow deny [!] aclname
Default	http_access deny all

Synopsis

This is used for filtering based on the acl matchings. If none of the "access" lines cause a match, the default is the opposite of the last line in the list. If the last line was deny, then the default is allow. Conversely, if the last line is allow, the default will be deny. For these reasons, it is a good idea to have an "deny all" or "allow all" entry at the end of your access lists to avoid potential confusion.

Arguments

allow/deny	Allow or deny on matching the acl		
aclname	Access list to be allowed/denied on match		

Example(s)

To allow http_access for only one machine with MAC Address 00:08:c7:9f:34:41

To restrict access to work hours (9am - 5pm, Monday to Friday) from IP 192.168.2/24

Can i use multitime access control list for different users for different timing

Rules are read from top to bottom

Note

The deny all line is very important. After all the http_access rules, if access isn't denied, it's ALLOWED!! So, specifying a LOT of http_access allow rules, and forget the deny all after them, is the same of NOTHING. If access isn't allowed by one of your rules, the default action (ALLOW) will be triggered. So, don't forget the deny all rule AFTER all the rules.

And, finally, don't forget rules are read from top to bottom. The first rule matched will be used. Other rules won't be applied.

Recommended minimum http_access configuration

http_access allow manager localhost

http_access deny manager

http_access deny !Safe_ports

http_access deny CONNECT !SSL_ports

http_access deny all

TAG NAME	http_access2
Description	Allowing or Denying access based on defined access lists
Build Option	Default
Usage	http_access2 allow deny [!] aciname
Default	none

Synopsis

Identical to http_access, but runs after redirectors. If not set then only http_access is used.

Arguments

allow/deny Allow or deny on matching		Allow or deny on matching the acl
	aclname	Access list to be allowed/denied on match

Example(s)

acl off_time time SMT 9.30 - 5.30 http_access2 allow all

http_access2 deny off_time

A	TAG NAME	http_reply_access			
Description This is complementary to http_access which allows or denies clients replies					
	Build Option	Default			
	Usage	http_reply_access allow deny [!] aclname			
	Default	http_reply_access allow all			

Synopsis

This is used for filtering based on the acl matchings but on the client requests reply. If none of the access lines cause a match, then the opposite of the last line will apply. Thus it is good practice to end the rules with an "allow all" or "deny all" entry.

Arguments

allow/deny	Allow or deny on matching the acl	
aclname	Access list to be allowed/denied on match	

Example(s)

acl reject urlpath_regex i home http_reply_access deny reject

TAG NAME	icp_access
Description	Allowing or Denying access to the ICP port based on defined access lists
Build Option	Default
Usage	icp_access allow deny [!] aclname
Default	icp_access deny all

This tag controls icp access on defined access lists.

Arguments

allow/deny	Allow or deny on matching the acl
aclname	Access list to be allowed/denied on match

Example(s)

icp_access allow all
Allows ICP queries from everyone.

TAG NAME	htcp_access
Description	Allowing or Denying access to the HTCP port based on defined access lists
Build Option	enable-htcp
Usage	htcp_access allow deny [!] aclname
Default	htcp_access deny all

Allowing or Denying access to the HTCP port based on defined access lists

See http_access for details

Arguments

allow/deny	Allow or deny on matching the acl
aclname	Access list to be allowed/denied on match

Example(s)
To allow HTCP queries from everyone

htcp_access allow all

TAG NAME	htcp_clr_access
Description	Allowing or Denying access to purge content using HTCP based on defined access lists
Build Option	enable-htcp
Usage	htcp_clr_access allow deny [!] aclname
Default	htcp clr access deny all

Allowing or Denying access to purge content using HTCP based on defined access lists

See http_access for details

Arguments

allow/deny	Allow or deny on matching the acl
aclname	Access list to be allowed/denied on match

Example(s)
Allow HTCP CLR requests from trusted peers acl htcp_clr_peer src 172.16.1.2
htcp_clr_access allow htcp_clr_peer

TAG NAME	miss_access
Description	Used to force your neighbours to use you as sibling instead of parent
Build Option	Default
Usage	miss_access allow deny [!] aclname
Default	miss_access allow all

Synopsis

This tag forces the neighbouring peers to treat you as sibling instead of parent.

Arguments

allow/deny	Allow or deny on matching the acl
aclname	Access list to be allowed/denied on match

Example(s) acl localclients src 172.16.0.0/16 miss_access allow localclients

miss_access deny!localclients
This means that only your local clients are allowed to fetch MISSES and all other clients can only fetch HITS.

Description	Similar to cache_peer_domain but provides more flexibility by using ACL elements
Build Option	Default
Usage	cache_peer_access cache-host allow deny [!]aclname
Default	none

The syntax is identical to http_access and the other lists of ACL elements. See http_access for further reference.

Arguments

allow/deny	Allow or deny on matching the acl
aclname	Access list to be allowed/denied on match

Example(s)

The following example could be used, if we want all requests from a specific IP address range to go to a specific cache server (for accounting purposes, for example). Here, all the requests from the 10.0.1.* range are passed to proxy.visolve.com, but all other requests are handled directly.

Using acls to select peers, acl myNet src 10.0.0.0/255.255.255.2 acl cusNet src 10.0.1.0/255.255.255.0 acl all src 0.0.0.0/0.0.0.0

cache_peer proxy.visolve.com parent 3128 3130 cache_peer_access proxy.visolve.com allow custNet

cache_peer_access proxy.visolve.com deny all

TAG NAME	ident_lookup_access
Description	A list of ACL elements which, if matched, cause an ident (RFC 931) lookup to be performed for this request
Build Option	Default
Usage	ident_lookup_access allow deny aclname
Default	ident_lookup_access deny all

Synopsis

This tag allows or denies ident lookups an matching the access lists.

Note: Only src type ACL checks are fully supported. A src_domain ACL might work at times, but it will not always provide the correct result. This option may be disabled by using --disable-ident-lookups with the configure script.

Arguments

allow/deny	Allow or deny on matching the acl
aclname	Access list to be allowed/denied on match

Example(s)

To enable ident lookups for specific client addresses, you can follow this example, acl ident_aware_hosts src 198.168.1.0/255.255.255.0 ident_lookup_access allow ident_aware_hosts

ident_lookup_access deny all

TAG NAME	tcp_outgoing_tos
Description	Allows you to select a TOS/Diffserv value to mark outgoing connections with, based on the username or source address making the request
Build Option	Default
Usage	tcp_outgoing_tos ds-field [!]aclname
Default	none

Synopsis

The TOS/DSCP byte must be exactly that - a byte, value 0 - 255, or "default" to use whatever default your host has. Processing proceeds in the order specified, and stops at first fully matching line.

Arguments

ds-fiels	Outgoing TOS value
aclname	Identifier that contains the list to match on

Example(s)

acl good_service_net src 10.0.1.0/255.255.255.0 tcp_outgoing_tos 0x20 good_service_net Here, good_service_net uses the TOS value 0x20

TAG NAME	tcp_outgoing_address
Description	Allows you to map requests to different outgoing IP addresses based on the username or source address of the user making the request
Build Option	Default
Usage	tcp_outgoing_address ipaddr [[!]aclname]
Default	none

Synopsis

Processing proceeds in the order specified, and stops at first fully matching line.

Arguments

ipaddr	Outgoing ip address
aclname	Access lists

Example(s)

acl normal_net src 172.16.1.0/24

tcp_outgoing_address 172.16.1.53 normal_net

Here requests from machines in network 172.16.1.0 will be sent as request from 172.16.1.53 to the origin server.

Description	This specifies the maximum size for HTTP headers in a reply.
Build Option	Default
Usage	reply_header_max_size size
Default	reply_header_max_size 20 KB

This specifies the maximum size for HTTP headers in a reply. Reply headers are usually relatively small (about 512 bytes). Placing a limit on the reply header size will catch certain bugs (for example with persistent connections) and possibly buffer-overflow or denial-of-service attacks.

Arguments

size	Maximum header body size	
------	--------------------------	--

Example(s)

reply_header_max_size 25 KB

TAG NAME	reply_body_max_size
Description	This option specifies the maximum size of a reply body
Build Option	Default
Usage	reply_body_max_size size [acl acl]
Default	none

Synopsis

Using this you can prevent users from downloading very large files, such as MP3's and movies.

- 1. Downstream caches probably can not detect a partial reply if there is no content-length header, so they will cache partial responses and give them out as hits. You should NOT use this option if you have downstream caches.
- 2. A maximum size smaller than the size of Squid's error messages will cause an infinite loop and crash Squid. Ensure that the smallest non-zero value you use is greater that the maximum header size plus the size of your largest error page.

Arguments

size	Maximum reply body size
acl	Access lists on which this functions during match

Example(s)

acl site url_regex -i ^http://www.visolve.com

reply_body_max_size 5 KB site

Here, the reply contains content-length. Its size is checked with the specified value. If it is greater then the specified range the an error page is displayed only for this site while access to other sites are allowed.

TAG NAME	log_access
Description	This options allows you to control which requests gets logged to access.log
Build Option	Default
Usage	log_access allow deny acl acl
Default	none

Synopsis

Sometimes you will not be interested in certain access to be logged in the access.log file. This can be implemented using this tag as follows.

Arguments

allow/deny	Allow or deny on matching the acl
aclname	Access list to be allowed/denied on match

Example(s)

acl google url_regex ^http://www.google.co.in

log_access deny google

access_log /usr/local/Squid3.0pre3/var/logs/access.log common google

This will not log access to http://www.google.co.in into the access.log file.

Example(s)

(1) To allow http_access for only one machine with MAC Address 00:08:c7:9f:34:41

To use MAC address in ACL rules. Configure with option -enable-arp-acl.

acl all src 0.0.0.0/0.0.0.0 acl pl800_arp arp 00:08:c7:9f:34:41 http_access allow pl800_arp

http_access deny all

(2) To restrict access to work hours (9am - 5pm, Monday to Friday) from IP 192.168.2/24

acl ip_acl src 192.168.2.0/24 acl time_acl time M T W H F 9:00-17:00 http_access allow ip_acl time_acl http://access.denv.all

(3) Can i use multitime access control list for different users for different timing.

Acl Defnitions.

acl abc src 172.161.163.85 acl xyz src 172.161.163.86 acl asd src 172.161.163.87 acl morning time 06:00-11:00 acl lunch time 14:00-14:30 acl evening time 16:25-23:59

Access Controls,

http_access allow abc morning http_access allow xyz morning lunch

http_access allow asd lunch

This is wrong. The description follows:

Here access line "http_access allow xyz morning lunch" will not work. So ACLs are interpreted like this ...

http_access RULE statement1 AND statement2 AND statement3 OR http_access ACTION statement1 AND statement2 AND statement3 OR

So, the ACL "http_access allow xyz morning lunch" will never work, as pointed, because at any given time, morning AND lunch will ALWAYS be false,

because both morning and lunch will NEVER be true at the same time. As one of them is false, and acl uses AND logical statement, 0/1 AND 0 will always be 0 (false).

That's because this line is in two. If now read,

http_access allow xyz AND morning OR

http_access allow xyz lunch

If request comes from xyz, and we're in one of the allowed time, one of the rules will match TRUE. The other will obviously match FALSE, TRUE OR

FALSE will be TRUE, and access will be permitted.

Finally Access Control looks.

http access allow abc morning

http_access allow xyz morning

http_access allow xyz lunch

http_access allow asd lunch

http_access deny all

(4) Rules are read from top to bottom. The first rule matched will be used. Other rules won't be applied.

http_access allow xyz morning

http_access deny xyz

http access allow xyz lunch

If xyz tries to access something in the morning, access will be granted. But if he tries to access something at lunchtime, access will

be denied. It will be

denied by the deny xyz rule, that was matched before the 'xyz lunch' rule.

ADMINISTRATIVE PARAMETERS

The parameters in this section allow the Squid admin to specify, for example, which users and groups have the right to run Squid , what host name should be displayed while displaying errors, which users have the authority to view Cache activity details, etc.

TAG NAME	cache_mgr
Description	This is to specify email address of the administrator of this cache
Build Option	Default
Usage	cache_mgr mail_id
Default	cache mgr webmaster

Synopsis

This is the address which will be added to any error pages that are displayed to clients. Defaults to either webmaster.

Arguments

mail_id	Mail id to be displayed
---------	-------------------------

Example(s)

cache_mgr Squidadmin@visolve.com

TAG NAME	mail_from
Description	Email-address for mail sent when the cache dies.
Build Option	Default
Usage	mail_from mail_id
Default	none

Synopsis

The default is to use 'appname@unique_hostname'. Default appname value is "squid", can be changed into src/globals.h before building squid.

Arguments

mail_id Mail id to be displayed

Example(s)

mail_from squid@vicachefilter.com

	TAG NAME	mail_program
Des	scription	Email program used to send mail if the cache dies.
Buil	ld Option	Default
Usa	nge	mail_program recipient < mailfile
Defa	ault	cache_mgr webmaster

Synopsis

The default is "mail". The specified program must complain with the standard Unix mail syntax: mail_program recipient < mailfile Optional command line options can be specified.

Arguments

program	Mail program to use
---------	---------------------

Example(s)

cache_mgr Squidadmin@visolve.com

TAG NAME	cache_effective_user, cache_effective_group
Description	The user name and group name Squid will operate as
Build Option	Default
Usage	cache_effective_user username cache_effective_group groupname
Default	cache_effective_user nobody cache_effective_group nogroup

Squid is designed to start as root but very soon after drop to the user/group specified here. This allows you to restrict, for security reasons, the permissions that Squid will have when operating. By default, Squid will operate as either nobody user and the nogroup group.

Note: If these tags are not configured properly, then Squid will have problems while starting.

Arguments

username	Username for Squid process
groupname	Group name for Squid process

Example(s)

cache_effective_user Squid cache_effective_group Squid

TAG NAME	httpd_suppress_version_string
Description	Suppress Squid version string info in HTTP headers and HTML error pages.
Build Option	Default
Usage	httpd_suppress_version_string on off
Default	httpd_suppress_version_string off

Synopsis

Suppress Squid version string info in HTTP headers and HTML error pages.

Arguments

on/off Enable/Disable the httpd suppress version string

TAG NAME	visible_hostname
Description	The host name that Squid will advertise itself on
Build Option	Default
Usage	visible_hostname anyname
Default	none

Synopsis

This effects the host name that Squid uses when serving error messages. This option may need to be configured in cache clusters if you receive IP-Forwarding errors.

Note: If not configured, Squid will not start.

Arguments

anyname Name of the Squid machine

Example(s)

visible_hostname SYS-CO1

TAG NAME	unique_hostname
Description	Used to set a unique host name for Squid to report in cache clusters in order to allow detection of forwarding loops
Build Option	Default
Usage	unique_hostname hostname
Default	none

Synopsis

If you want to have multiple machines with the same <u>visible_hostname</u> then you must give each machine a different <u>unique_hostname</u> so that forwarding loops can be detected. In brief, Just set <u>visible_hostname</u> to the address the clients connects to, and <u>unique_hostname</u> to the externally visible address of each proxy. (address == registered domain name).

Arguments

hostname Unique name of the Squid machine

Example(s)

unique_hostname www.kovaiteam.com

	TAG NAME	hostname_aliases
	Description	Used to list of other DNS names that your cache has
ı	Build Option	Default
	Usage	hostname_aliases name
	Default	none

There may be situations where you system or cache have more than one DNS names. In such situations you may specify the DNS names in this tan

Arguments

name Alias name

Example(s)

hostname_aliases rose

TAG NAME	umask
Description	Minimum umask which should be enforced while the proxy is running, in addition to the umask set at startup.
Build Option	Default
Usage	umask value
Default	umask 027

Synopsis

Minimum umask which should be enforced while the proxy is running, in addition to the umask set at startup.

None

Should start with a 0 to indicate the normal octal representation of umasks

Arguments

value umask which should be enforced while the proxy is running

Example(s)

umask 030

CACHE REGISTRATION SERVICE

This section contains configurations needed for the (optional) cache announcement service. This service is provided to help cache administrators locate one another in order to join or create cache hierarchies. An *announcement* message is sent (via UDP) to the registration service by Squid. By default, the announcement message is NOT SENT unless you enable it with *announce_period* below.

All current information is processed regularly and made available on the Web at http://www.ircache.net/Cache/Tracker/.

TAG NAME	announce_period
Description	Defines the rate of sending announcement messages
Built Option	Default
Usage	announce_period units
Default	announce_period 0

Synopsis

This tag refers to the frequency at which Squid will send announcement messages to the announce host. Defaults to 0 which stops sending announcement messages.

Arguments

units	Announce time period

Example(s)

announce_period 10

TAG NAME	announce_host
Description	Used to define the host address to which Squid will send announcement message to participate in the cache hierarchy
Built Option	Default
Usage	announce_host hostname
Default	announce_host tracker.ircache.net

Synopsis

announce_host defines the host for sending announcement messages to get participated in the cache hierarchy.

Arguments

hostname Host name for announcement message

Example(s)

announce_host cache.ircache.net

TAG NAME	announce_port
Description	Port through which Squid sends announcement message to participate in the cache hierarchy
Built Option	Default
Usage	announce_port portnumber
Default	announce_port 3131

Synopsis

announce_port defines the port to send announcement message for participating in the cache hierarchy.

Arguments

portnumber Port where Squid binds the socket

Example(s)

announce_port 3132

I AG NAME	announce_file
Description	Defines the file whose contents to be sent along with the announcements
Built Option	Default
Usage	announce_file filename
Default	

announce_file contains message to be sent with announcements.

Arguments

filename File whose content to be sent

Example(s)

announce_file /usr/local/file1

HTTPD ACCELERATOR SERVICE

In this acceleration mode, if the Web Server runs on the same server where Squid is installed, you must set its daemon to run on port 81. With the Apache web server, you can do it by assigning the line Port 80 to Port 81 in its httpd.conf file. If the Web Server runs on other servers in your network like we do, you can keep the same port number (80) for Apache, since Squid will bind on a different IP number where port (80) is not already in use.

TAG NAME	httpd_accel_no_pmtu_disc
Description	Defines the rate of sending announcement messages
Built Option	Default
Usage	announce_period units
Default	announce_period 0

Synopsis

This tag refers to the frequency at which Squid will send announcement messages to the announce host. Defaults to 0 which stops sending announcement messages.

Arguments

units Announce time period

Example(s)

announce_period 10

MISCELLANEOUS

This section covers configurations that could not be explicitly bundled in with any of the previous categories. Examples of features covered here are limiting the growth of log files, displaying customized information to clients upon error conditions or access denial, defining memory pools for Squid, network management by enabling SNMP, co-ordination with neighbor caches by enabling WCCP, directing the requests either to the origin server or to the neighbor cache, etc.

TAG NAME	dns_testnames
Description	This points to a number of hosts that Squid can use to test if DNS service is working properly on your network
Build Option	Default
Usage	dns_testnames url
Default	dns_testnames netscape.com internic.net nlanr.net microsoft.com

Synopsis

If DNS isn't working properly, Squid will not be able to service requests, so it will refuse to start, with a brief message regarding why in the cache.log. It is recommended that you select two or more host names on the internet and one or two host names on your intranet, assuming you have one and Squid is expected to service it. By default, the dns_testnames directive checks a few well known and popular sites: netscape.com, internic.net, nlanr.net, and microsoft.com.

Arguments

url Sites on which DNS test to be done

Example(s)

dns_testnames visolve.com

TAG NAME	logfile_rotate
Description	Used to specify the number of old rotated log files Squid will keep
Build Option	Default
Usage	logfile_rotate number
Default	logfile_rotate 10

Synopsis

The value in this tag defines number of rotated log files to be generated. This defaults to 10, which means Squid will keep 10 old log files before overwriting the oldest. **Squid -k rotate** is the command line usage to implement this function.

Arguments

number Number of rotations

Example(s)

logfile_rotate 5

Description	The domain that Squid will append to requests that are not possibly fully qualified domain names (more precisely, those that have no dots in them)
Build Option	Default
Usage	append_domain domainname
Default	none

Using this tag, you can append the domain names to the requests that are not fully qualified domains names.

Note: append_domain must begin with a period.

Arguments

dimainname Domain name to be appended

Example(s)

append_domain .cgi.com

TAG NAME	tcp_recv_bufsize
Description	Defines the size of the buffer used for TCP packets being received
Build Option	Default
Usage	tcp_recv_bufsize bytes
Default	tcp_recv_bufsize 0 bytes

Synopsis

When defined to a non-zero value, this determines the TCP packets receiving buffer size. By default Squid uses whatever the default buffer size for your operating system is. This is done by setting its value to zero.

Arguments

bytes Buffer size

Example(s)

tcp_recv_bufsize 500 bytes

TAG NAME	error_map
Description	Map errors to custom messages
Build Option	Default
Usage	error_map message_url http_status
Default	none

Synopsis

Use in accelerators to substitute the error messages returned by servers with other custom errors.

In Addition the following headers are forwarded from the client request: User-Agent, Cookie, X-Forwarded-For, Via, Authorization, Accept, Referer

And the following headers from the server reply:

Server, Via, Location, Content-Location

The reply returned to the client will carry the original HTTP headers from the real error message, but with the reply body of the configured error message.

Arguments

message_url The received HTTP status code (i.e. 404)
http_status The requested URI where the error occurred

Example(s)

error_map http://visolve.com/error/404.shtml 404

TAG NAME	err_html_text
Description	Provides a means to automatically add some extra information to Squid's error pages
Build Option	Default
Usage	err_htmal_text text
Default	none

Synopsis

You can add HTML or plain text comments or links here, which will be added to the error messages displayed to clients. To include this in your error messages, you must rewrite the error template files (found in the "errors" directory). Wherever you want the err_html_text line to appear, insert a %L tag in the error template file.

Arguments

text Message to be displayed

Example(s)

err_html_text squid@visolve.com

Consider you want to display this mail Id when access denied error occurs, then edit the corresponding file (ERR_ACCESS_DENIED in '\$prefix/etc/errors' directory) with %L where this mail Id should be displayed.

TAG NAME deny_info

Description	Used to define a customized error page for the requests which gets denied by http_access rules
Build Option	Default
Usage	deny_info err_page_name acl deny_info link acl
Default	none

You might have defied certain rules which filters access to certain domains. While accessing those domains, Squid normally displays a default error page. Using this tag, we can define a customized error page.

Arguments

err_page_name	Customized error page to be displayed
acl	acl for which the page to be displayed
link	Link to be displayed on deny access

Example(s)

acl test1 urlpath_regex -i .index.html

http_access deny test1

deny_info http://www.google.co.in test1

On satisfying http_access, instead of the default error page, the site google will be loaded.

A	TAG NAME	memory pools
	TAGINAME	memory_pools
	Description	This allows Squid to keep memory that it has allocated (but no longer needs), so that it will not need to reallocate memory in the future
	Build Option	Default
	Usage	memory_pools on off
	Default	memory pools on

Synopsis

Memory pools can improve performance to a small margin by allocating memory, but may need to be turned off if memory is at a premium on your system. This option defaults to on.

Arguments

on/off Enable or disable memory pool feature

TAG NAME	memory_pools_limit
Description	The amount of memory Squid will keep allocated, assuming the Keep memory for future use option is turned on
Build Option	Default
Usage	memory_pools_limit bytes
Default	none

Synopsis

Any non-zero value to this tag will instruct Squid not to keep more than that amount allocated, and if Squid requires more memory than that to fulfill a request, it will use your system's malloc library. Squid does not pre-allocate memory, so it is safe to set this reasonably high. If your Squid runs on a dedicated host, it is probably wisest to leave it to its default of unlimited. If it must share the system with other server processes (like Apache or Sendmail) then it might be appropriate to limit it somewhat.

Arguments

bytes Memory pool limit size

Example(s)

memory_pools_limit 50 MB

TAG NAME	via	
Description	Enable/disable via header	
Build Option	Default	
Usage	via on off	
Default	via on	

Synopsis

If set (default), Squid will include a Via header in requests and replies as required by RFC2616.

Arguments

on/off Enable/disable via header

TAG NAME	forwarded_for
Description	This option allows you to choose whether Squid will report the host name of the system that originally made the request to the origin server
Build Option	Default
Usage	forwarded_for on off
Default	forwarded_for on

If set, Squid will include your system's IP address or name in the HTTP requests it forwards. By default it looks like this: X-

Forwarded-For: 192.1.2.3

If you disable this, it will appear as X-Forwarded-For: unknown

Arguments

Enable or disable forwarding on/off

Description	Dictates whether Squid will log ICP requests
Build Option	Default
Usage	log_icp_queries on off
Default	log icp queries on

When you fell if ICP loads are very high, you can disable it otherwise you can enable for logging ICP requests.

Arguments

on/off Enable or disable logging ICP queries

TAG NAME	icp_hit_stale
Description	Enable/disable to return ICP_HIT for stale cache objects
Build Option	Default
Usage	icp_hit_stale on off
Default	icp hit stale off

Synopsis

If you want to return ICP_HIT for stale cache objects, set this option to 'on'. If you have sibling relationships with caches in other administrative domains, this should be 'off'. If you only have sibling relationships with caches under your control, then it is probably okay to set this to 'on'. If set to 'on', then your siblings should use the option "allow-miss" on their cache peer lines for connecting to you.

Arguments

on/off Enable or disable icp stale hit

TAG NAME	minimum_direct_hops
Description	Define minimum number of direct hops after which it directs Squid to do direct fetches
Build Option	Default
Usage	minimum_direct_hops number
Default	minimum_direct_hops 4

Synopsis

When using ICMP pinging features of Squid to determine distance to peers and origin servers, this configures when Squid should prefer going direct over a peer. This parameter plays a role in deciding latency.

Arguments

number Number of hops

Example(s)

minimum_direct_hops 10

TAG NAME	minimum_direct_rtt
Description	Defines minimum rtt after which it directs Squid to do direct fetches
Build Option	Default
Usage	minimum_direct_rtt timeunits
Default	minimum_direct_rtt 400

Synopsis

If using the ICMP pinging stuff, do direct fetches for sites which are no more than this many rtt milliseconds away.

Arguments

timeunits Round Trip Time

Example(s)

minimum_direct_rtt 200

TAG NAME	cachemgr_passwd
Description	Specify passwords for cachemgr operations
Build Option	Default
Usage	cachemgr_passwd password action action
Default	none

Synopsis

By using this we can have secured administration over the Squid.

Actions:

5min, 60min, asndb, authenticator, cbdata, client_list, comm_incoming, config * , counters, delay, digest_stats, dns, events, filedescriptors, fqdncache, histograms, http_headers, info, io, ipcache, mem, menu, netdb, non_peers, objects, offline_toggle * , pconn, peer_select, redirector, refresh, server_list, shutdown * , store_digest, storedir, utilization, via_headers, vm_objects.

* Indicates actions which will not be performed without a valid password, others can be performed if not listed here.

To disable an action, set the password to "disable". To allow performing an action without a password, set the password to "none".

Use the keyword "all" to set the same password for all actions.

Arguments

password	Password for the action
action	Action as described above

Example(s)

cachemgr_passwd secret shutdown

TAG NAME	store_avg_object_size
Description	Average object size, used to estimate number of objects your cache can hold.
Build Option	Default
Usage	store_avg_object_size size(Kbytes)
Default	store avg object size 13 KB

To Estimate the number of objects your cache can hold: NUM_OBJ = cache_swap / store_avg_object_size where, cache_swap is the size of the cache.

Arguments

Size of the object size

Example(s)

store_avg_object_size 100 KB

TAG NAME	store_objects_per_bucket
Description	Defines the number of objects in each store hash table
Build Option	Default
Usage	store_objects_per_bucket number
Default	store_objects_per_bucket 20

Synopsis

Target number of objects per bucket in the store hash table. Lowering this value increases the total number of buckets and also the storage maintenance rate.

Arguments

Number of objects number

Example(s)

store_objects_per_bucket 50

TAG NAME	client_db
Description	Allows you to choose whether Squid will keep statistics regarding each individual client
Build Option	Default
Usage	client_db on off
Default	client_db on

Synopsis

If you want to disable collecting per-client statistics, then turn off client_db here.

Arguments

Enable or disable collecting client statistics on/off

TAG NAME	netdb_low, netdb_high
Description	Defines low and high water marks for the ICMP measurement database
Build Option	Default
Usage	netdb_low number netdb_high number
Default	netdb_low 900 netdb_high 1000

Synopsis

These measurements are counts and not percentage. The defaults are 900 and 1000. When the high water mark is reached, database entries will be deleted until the low mark is reached.

Arguments

number Number of entries

Example(s) netdb_low 500 netdb_high 800

TAG NAME	netdb_ping_period
Description	Defines minimum period for measuring a site
Build Option	Default
Usage	netdb_ping_period timeunits
Default	netdb_ping_period 5 minutes

Synopsis

When this is defined, there will be at least this much delay between successive pings to the same network. The default is five minutes.

Arguments

timeunits Time period between successive pings

Example(s)

netdb_ping_period 15 minutes

Description	Enabling this option, makes Squid to ask your peers to include ICMP data in their ICP replies
Build Option	enable-icmp
Usage	query_icmp on off
Default	query_icmp off

If your peer has configured Squid (during compilation) with '--enable-icmp' then that peer will send ICMP pings to origin server sites of the URLs it receives. If you enable this option then the ICP replies from that peer will include the ICMP data (if available). Then, when choosing a parent cache, Squid will choose the parent with the minimal RTT to the origin server. When this happens, the hierarchy field of the access.log will be "CLOSEST_PARENT_MISS". This option is off by default.

Arguments

on/off Enable or disable this option

T/	AG NAME	test_reachability
Descri	ption	When this is 'on', ICP MISS replies will be ICP_MISS_NOFETCH instead of ICP_MISS if the target host is NOT in the ICMP database, or has a zero RTT
Build C	Option	Default
Usage		test_reachability on off
Default	t	test_reachability off

Synopsis

If the target host is NOT in the ICMP database, or has a zero RTT, enabling this tag, ICP MISS replies will be ICP_MISS_NOFETCH instead of ICP_MISS.

Arguments

on/off Enable or disable

TAG NAME	buffered_logs
Description	Buffering and unbuffering can be done while writing cache.log with stdio functions using this tag
Build Option	Default
Usage	buffered_logs on off
Default	buffered_logs off

Synopsis

Buffering it can speed up the writing slightly. By default it will be unbuffered.

Arguments

on/off Enable or disable buffering

A	TAG NAME	reload_into_ims
	Description	When you enable this option, client no-cache or reload requests will be changed to If-Modified-Since requests
	Build Option	Default
	Usage	reload_into_ims on off
	Default	reload_into_ims off

Synopsis

This tag is used to change clients no-cache or reload requests to IMS(if-modified sequence).

Note: Enabling this feature could make you liable for problems which it causes.

Arguments

on/off Enable or disable

TAG NAME	always_direct
Description	Here you can use ACL elements to specify requests which should ALWAYS be forwarded directly to origin servers
	Default always_direct allow deny [!]aclname
	none

Synopsis

Allows you to easily pick which ACL matches will not be cached. Requests that match the selected ACLs will always be answered from the origin server. Example below explains the tag to a clear extent.

Arguments

allow/deny	Allow or deny direct access
aclname	Access list on which this should act

Example(s)

acl local-servers dstdomain my.domain.net always_direct allow local-servers

To always forward FTP requests directly, use acl FTP proto FTP always_direct allow FTP

Description	With never_direct you can use ACL elements to specify requests which should NEVER be forwarded directly to origin servers
Build Option	Default
Usage	never_direct allow deny [!] aclname
Default	none

never_direct is the opposite of always_direct. By default all requests are not forwarded directly to the origin server.

The following example explains this tag.

Arguments

allow/deny	Deny or allow direct access
aclname	Access list on which this should act

Example(s)

To force the use of a proxy for all requests, except those in your local domain use something like acl local-servers dstdomain .foo.net acl all src 0.0.0.0/0.0.0.0 net never_direct deny local-servers never_direct allow all

or if Squid is inside a firewall and there is local intranet servers inside the firewall then use something like:

acl local-intranet dstdomain .foo.net acl local-external dstdomain external.foo.net always_direct deny local-external always_direct allow local-intranet never_direct allow all

TAG NAME	header_access [previously called as anonymous_headers in 2.5 & http_anonymiser in 2.4]
Description	This creates a list of ACLs for each header, allowing you very fine-tuned header mangling
Build Option	Default
Usage	header_access allow deny header_name
Default	none

Synopsis

This option replaces the old 'anonymize_headers' and the older 'http_anonymizer' option with something that is much more configurable. This new method creates a list of ACLs for each header, allowing you very fine-tuned header mangling.

You can only specify known headers for the header name. Other headers are reclassified as 'Other'. You can also refer to all the headers with 'All'.

Arguments

allow/deny	Allow or deny access for the specified header name
header name	Header name

Example(s)

header_access Proxy-Connection allow all

TAG NAME	header_replace
Description	This option allows you to change the contents of headers denied with header_access above
Build Option	Default
Usage	header_replace header_name message
Default	none

Synopsis

For headers denied with header_access, this tag allows to replace the content of the header using the message specified This is done by replacing them with some fixed string. This replaces the old fake_user_agent option. By default, headers are removed if denied.

Arguments

header_name	Header for which content to be changed
message	Content to be replaced with the message specified here

Example(s)

header_replace User-Agent Nutscrape/1.0 (CP/M; 8-bit)

_	$\overline{}$		
		,	

TAG NAME	icon_directory
Description	Used to specify the path to icon deirectory
Build Option	Default
Usage	icon_directory path/directoryname
Default	icon_directory /usr/local/Squid/share/icons

Synopsis

This tag is used to indicate the icon directory.

Arguments

path/directoryname Location path and name of the directory

Example(s)

icon_directory /usr/local/icons

Description	Used to control, is Squid should intercept all requests for /squid-internal-static/ no matter which host the URL is requesting (default on setting), or if nothing special should be done for such URLs (off setting).
Build Option	Default
Usage	global_internal_static on off
Default	global_internal_static on

Used to control, is Squid should intercept all requests for /squid-internal-static/ no matter which host the URL is requesting (default on setting), or if nothing special should be done for such URLs (off setting).

The purpose of this directive is to make icons etc work better in complex cache hierarchies where it may not always be possible for all corners in the cache mesh to reach the server generating a directory listing.

Arguments

on/off Enable or Disable the globel internal static

TAG NAME	short_icon_urls
Description	Enables squid to use short URL's for Icons
Build Option	Default
Usage	short_url_icons on off
Default	short_icon_urls off

Synopsis

If this is enabled Squid will use short URLs for icons.

If off the URLs for icons will always be absolute URLs including the proxy name and port.

Arguments

on/off Enable or Disable the short URL's

TAG NAME	error_directory
Description	Defines path to your own error directory
Build Option	Default
Usage	error_directory path/directoryname
Default	error_directory /usr/local/Squid/share/errors/English

Synopsis

Used to specify location and name of the error directory used.

Arguments

path/directoryname Location path and name of the directory

Example(s)

error_directory /usr/local/error

TAG NAME	maximum_single_addr_tries
Description	This sets the maximum number of connection attempts for a host that has only one address
Build Option	Default
Usage	maximum_single_addr_tries number
Default	maximum_single_addr_tries 3

Synopsis

If the host has more number of address (for multiple-address hosts), each address is tried once. The default value is three tries, the (not recommended) maximum is 255 tries.

Note

A warning message will be generated if it is set to a value greater than ten.

Arguments

number Number of tries

Example(s)

maximum_single_addr_tries 5

TAG NAME	retry_on_error
Description	If set to on Squid will automatically retry requests when receiving an error response.
Build Option	Default
Usage	retry_on_error on off
Default	retry_on_error off

Synopsis

If set to on Squid will automatically retry requests when receiving an error response. This is mainly useful if you are in a complex cache hierarchy to work around access control errors.

Arguments

on/off Enable / Disable Retry requests

Description	Squid serves statistics and status information via SNMP defined using this tag	
Build Option	enable-snmp	
Usage	snmp_port port_number	
Default	snmp_port 3401	

By default it listens to port 3401 on the machine. If you don't wish to use SNMP, set this to "0".

Arguments

Example(s)

snmp_port 3401

TAG NAME	snmp_access
Description	Access to SNMP port is controlled using this tag
Build Option	enable-snmp
Usage	snmp_access allow deny [!]aclname
Default	snmp_port 3401

Synopsis

All access to the agent is denied by default.

Arguments

allow/deny	Allow or deny access
aclname	Access list this should act on

Example(s)

 $\begin{array}{l} snmp_access \ allow \ snmppublic \ localhost \\ snmp_access \ deny \ all \end{array}$

TAG NAME	snmp_incoming_address, snmp_outgoing_address
Description	Defines the interface for snmp incoming and outgoing requests
Build Option	enable-snmp
Usage	snmp_incoming_address ip_address snmp_outgoing_address ip_address
Default	snmp_incoming_address 0.0.0.0 snmp_outgoing_address 255.255.255

Synopsis

The default snmp_incoming_address (0.0.0.0) is to listen on all available network interfaces. If snmp_outgoing_address is set to 255.255.255.255 (the default) then it will use the same socket as snmp_incoming_address. Only change this if you want to have SNMP replies sent using another address than where this Squid listens for SNMP queries.

Note: snmp_incoming_address and snmp_outgoing_address can not have the same value since they both use port 3401.

Arguments

ip_address Incoming and outgoing interface address

Example(s)

snmp_incoming_address 172.16.1.35 snmp_outgoing_address 172.16.1.36

TAG NAME	as_whois_server	
Description	This is to query AS numbers	
Build Option	Default	
Usage	as_whois_server_server_name	
Default	as whois server whois ra.net	

Synopsis

AS numbers are queried only when Squid starts up, not for every request.

Arguments

server_name | Server name for which AS numbers to be queried

Example(s)

as_whois_server ra.net

TAG NAME	wccp_router
Description	To define your WCCP "home" router for Squid
Build Option	Default
Usage	wccp_router ip_address
Default	wccp_router 0.0.0.0

Synopsis

Setting the wccp_router to 0.0.0.0 (the default) disables WCCP.

Arguments

ip_address | ip address of the router

Example(s)

wccp_router 172.16.1.100

Description	To define your WCCP "home" router for Squid, supports multiple WCCPv2 routers
Build Option	Default
Usage	wccp2_router ip_address
Default	wccp2_router 0.0.0.0

wccp2_router supports multiple WCCPv2 routers

only one of the two may be used at the same time and defines which version of WCCP to use.

Arguments

ip_address	ip address of the router	_
------------	--------------------------	---

Example(s)

wccp2_router 172.16.1.100

	TAG NAME	wccp_version
ı	Description	Used to specify the version of Cisco IOS used in the Router
E	Build Option	Default
ι	Jsage	wccp_version_version_number
- 1	Default	wccp_version 4

Synopsis

According to some users, Cisco IOS 11.2 only supports WCCP version 3. If you're using that version of IOS, change this value to 3.

Arguments

version_number	IOS version number

Example(s)

wccp_router 172.16.1.100

TAG NAME	wccp2_rebuild_wait
Description	Allows squid to wait for the cache dir rebuild to finish before sending the first wccp2 HerelAm packet.
Build Option	Default
Usage	wccp2_rebuild_wait on off
Default	wccp2_rebuild_wait on

Synopsis

If this is enabled Squid will wait for the cache dir rebuild to finish before sending the first wccp2 HerelAm packet.

Arguments

on/off Enable/Disable rebuild Wait	
------------------------------------	--

TAG NAME	wccp2_forwarding_method
Description	Allows the setting of forwarding methods between the router/switch and the cache.
Build Option	Default
Usage	wccp2_forwarding_method version_number
Default	wccp2_forwarding_method 1

Synopsis

WCCP2 allows the setting of forwarding methods between the router/switch and the cache.

Currently (as of IOS 12.4) cisco routers only support GRE. Cisco switches only support the L2 redirect assignment method.

Arguments

Arguments		
	1	GRE encapsulation (forward the packet in a GRE/WCCP tunnel)
	2	L2 redirect (forward the packet using Layer 2/MAC rewriting)

Example(s)

wccp2_forwarding_method 2

TAG NAME	wccp2_return_method
Description	Allows the setting of return methods between the router/switch and the cache for packets that the cache decides not to handle.
Build Option	Default
Usage	wccp2_return_method version_number
Default	wccp2_return_method 1

Synopsis

WCCP2 allows the setting of forwarding methods between the router/switch and the cache.

Currently (as of IOS 12.4) cisco routers only support GRE.

Cisco switches only support the L2 redirect assignment method.

If the "ip wccp redirect exclude in" command has been enabled on the cache interface, then it is still safe for the proxy server to use a I2 redirect method even if this option is set to GRE.

Arguments

1	GRE encapsulation (forward the packet in a GRE/WCCP tunnel)
2	L2 redirect (forward the packet using Layer 2/MAC rewriting)

Example(s)

wccp2_return_method 2

TAG NAME	wccp2_assignment_method
Description	Allows the setting of methods to assign the WCCP hash
Build Option	Default
Usage	wccp2_assignment_method version_number
Default	wccp2_assignment_method 1

WCCP2 allows the setting of methods to assign the WCCP hash

As a general rule, cisco routers support the hash assignment method and cisco switches support the mask assignment method.

Arguments

1	Hash assignment
2	Mask assignment

Example(s)

wccp2_assignment_method 2

TAG NAME	wccp2_service
Description	Allows for multiple traffic services.
Build Option	Default
Usage	wccp2_service version_number
Default	wccp2_service standard 0

Synopsis

WCCP2 allows for multiple traffic services.

MD5 service authentication can be enabled by adding "password=<password>" to the end of this service declaration.

Arguments

standard	Defines one service id - http (id 0).
dynamic	Defines the ids can be from 51 to 255 inclusive. In order to use a dynamic service id one must define the type of traffic to be redirected.

Note

The "standard" type does not require a wccp2_service_info option, just specifying the service id will suffice. In order to use a dynamic service id one must define the type of traffic to be redirected; this is done using the wccp2_service_info option.

Example(s)

wccp2_service standard 0

wccp2_service standard 80

wccp2_service standard 0 password=foo

TAG NAME	wccp2_service_info
Description	Used in Dynamic wccp2 service to give the information to define the traffic to be diverted
Build Option	Default
Usage	wccp2_service_info <id> protocol=<protocol> flags=<flag>,<flag> priority=<priority> ports=<port></port></priority></flag></flag></protocol></id>
Default	none

Synopsis

Dynamic WCCPv2 services require further information to define the traffic to be diverted

The port list can be one to eight entries.

Arguments

#	Flags
1	src_ip_hash, dst_ip_hash
2	source_port_hash, dest_port_hash
3	src_ip_alt_hash, dst_ip_alt_hash
4	src_port_alt_hash, dst_port_alt_hash
5	ports_source

Note

The service id must have been defined by a previous 'wccp2_service dynamic <id>'entry.

Example(s

wccp2_service_info 80 protocol=tcp flags=src_ip_hash,ports_source priority=240 ports=80

TAG NAME	wccp2_weight
Description	Each cache server gets assigned a set of the destination hash proportional to their weight.
Build Option	Default
Usage	wccp2_weight weight
Default	wccp2_weight 10000

Synopsis

Each cache server gets assigned a set of the destination hash proportional to their weight.

Example(s)

wccp2_weight 20000

Description	Option to give the specfic interface address to the WCCP
Build Option	Default
Usage	wccp_address ip wccp2_address ip
	wccp_address 0.0.0.0 wccp2_address 0.0.0.0

Use this option if you require WCCP to use a specific interface address.

The default behavior is to not bind to any specific address.

Example(s)

wccp_address 172.16.1.43 wccp2_address 172.16.1.32

DELAY POOL PARAMETERS

Conceptually, delay pools are bandwidth limiters - "pools" of bandwidth that drain out as people browse the Web, and fill up at the rate specified - this can be thought of as a leaky bucket that is continually being filled. This is useful when bandwidth charges are in place, if we want to reduce bandwidth usage for web traffic.

Delay Pools can do wonders when combined with ACLs. These tags permit us to limit the bandwidth of certain requests, based on any criteria. Delay behavior is selected by ACLs (low and high priority traffic, staff Vs students or student Vs authenticated student or so on). In ISPs, delay pools can be implemented in a particular network to improve the quality of service. To enable this, Squid needs to be configured with the --enable-delay-pools option.

TAG NAME	delay_pools
Description	Used to specify number of delay pools
Built Option	enable-delay-pools
Usage	delay_pools number
Default	delay_pools 0

Synopsis

This represents the number of delay pools to be used. For example, if you have one class 2 delay pool and one class 3 delays pool, you have a total of 2 delay pools.

Arguments

Number of delay pools number

Example(s)

delay_pools 5

TAG NAME	delay_class	
Description	This defines the class of each delay pool	
Built Option	enable-delay-pools	
Usage	delay_class pool-number class-number	
Default	none	

Synopsis

Class of the delay pool used is defined using this tag. There must be exactly one delay_class line for each delay pool. There are five categories of delay classes.

class 1	Everything is limited by a single aggregate bucket.
class 2	Everything is limited by a single aggregate bucket as well as an "individual" bucket chosen from bits 25 through 32 of the IP address.
class 3	Everything is limited by a single aggregate bucket as well as a "network" bucket chosen from bits 17 through 24 of the IP address and a "individual" bucket chosen from bits 17 through 32 of the IP address.
class 4	Everything in a class 3 delay pool, with an additional limit on a per user basis. This only takes effect if the username is
	established in advance - by forcing authentication in your http_access rules.
class 5	Requests are grouped according their tag (see external_acl tag= reply).

If an IP address is a.b.c.d

- -> bits 25 through 32 are "d"
- -> bits 17 through 24 are "c"
- -> bits 17 through 32 are "c * 256 + d"

Arguments

pool-number	Delay pool number
class-number	Delay class number

Example(s)

delay_pools 2

delay_class 1 2 (pool 1 is a class 2 pool) delay_class 2 3 (pool 2 is a class 3 pool)

TAG NAME

delay_access

Description	This is used to determine which delay pool a request falls into
Built Option	enable-delay-pools
Usage	delay_access delay_pool allow/deny domainname
Default	none

The first matched delay pool is always used, i.e., if a request falls into delay pool number one, no more delay are checked, otherwise the rest are checked in order of their delay pool number until they have all been checked.

Arguments

delay_pool	Delay pool number
allow/deny	Allow or deny access
domainname	Domain name on which this should act

Example(s)

If you want some_big_clients in delay pool 1 and lotsa_little_clients in delay pool 2:

delay_access 1 allow some_big_clients delay_access 1 deny all delay_access 2 allow lotsa_little_clients

delay_access 2 deny all delay_access 3 allow authenticated_clients

TAG NAME	delay_parameters
Description	Defines the parameters for a delay pool
Built Option	enable-delay-pools
Usage	delay_parameters pool aggregate (In general). For detailed format refer usage syntax bellow
Default	none

Synopsis

Using this tag, delay parameters for each each delay pool has a number of "buckets" associated with it, as explained in the description of delay_class.

Usage syntax for each class:	
class 1	delay_parameters pool aggregate
class 2	delay_parameters pool aggregate individual
class 3	delay_parameters pool aggregate network individual
class 4	delay_parameters pool aggregate network individual user
class 5	delay_parameters pool tag

A pair of delay parameters is written restore/maximum, where restore is the number of bytes (not bits - modem and network speeds are usually quoted in bits) per second placed into the bucket, and maximum is the maximum number of bytes which can be in the bucket at any time.

Arguments

3	
pool	Delay pool number - ie, a number between 1 and the number specified in <u>delay_pools</u> as used in <u>delay_class</u> lines.
aggregate	the "delay parameters" for the aggregate bucket (class 1, 2, 3).
individual	the "delay parameters" for the network buckets (class 3).
user	user on which this condition is applied
tag	the delay parameters for the tag buckets (class 5).

Example(s)

If delay pool number 1 is a class 2 delay pool is being used to strictly limit each host to 64kbps (plus overheads), with no overall limit, the usage is,

delay_parameters 1 -1/-1 8000/8000

For a class 4 delay pool, each user will be limited to 128 Kbs no matter how many workstations they are logged into: delay_parameters 4 32000/32000 8000/8000 600/64000 16000/16000

TAG NAME	delay_initial_bucket_level
Description	Used to determine how much data is put in each bucket when Squid starts, is reconfigured, or first notices a host accessing it
Built Option	enable-delay-pools
Usage	delay_initial_bucket_level percent(0-100)
Default	delay_initial_bucket_level 50

Synopsis

The initial bucket percentage is used to determine how much is put in each bucket when Squid starts, is reconfigured, or first notices a host accessing it. In class 2 and class 3, individual hosts and networks only have buckets associated with them once they have been "seen" by Squid

Arguments

		-1
percent	Initial bucket level in percentage	

Example(s)

delay_initial_bucket_level 20

TAG NAME

incoming_icp_average, incoming_http_average,	
incoming_dns_average, min_icp_poll_cnt, min_dns_poll_cnt,	
min_http_poll_cnt	

Description	Using these tags, average number of ICP, HTTP requests, their polling rates can be specified
Built Option	enable-delay-pools
Usage	Tagname number
Default	incoming_icp_average 6 incoming_http_average 4 incoming_dns_average 4 min_icp_poll_cnt 8 min_dns_poll_cnt 8 min_http_poll_cnt 8

INCOMING sockets are the ICP and HTTP ports. Squid need to check these fairly regularly, but how often? When the load increases, Squid want to check the incoming sockets more often. If Squid have a lot of incoming ICP, then it needs to check these sockets more than if we just have HTTP. These change of algorithms by Squid are decided by these tags.

Arguments

Number Number to change the algorithm used by Squid

Example(s)

incoming_icp_average 3 incoming_http_average 2 incoming_dns_average 3 min_icp_poll_cnt 8 min_dns_poll_cnt 6 min_http_poll_cnt 6

TAG NAME	max_open_disk_fds
Description	Defines number of file descriptors to be handled directly
Built Option	Default
Usage	max_open_disk_fds number
Default	max_open_disk_fds 0

To avoid having disk as the I/O bottleneck Squid can optionally bypass the on-disk cache if more than this amount of disk file descriptors are open.

A value of 0 indicates no limit.

Arguments

number Maximum number of file descriptors

Example(s)

max_open_disk_fds 5

TAG NAME	offline_mode
Description	When enabled, Squid will never try to validate cached objects.
Built Option	Default
Usage	offline_mode on off
Default	offline_mode off

Synopsis

offline_mode gives access to more cached information than the proposed feature would allow (stale cached versions, where the origin server should have been contacted).

Arguments

on/off Enable or disable offline_mode feature

TAG NAME	uri_whitespace
Description	Used to specify the action of Squid when the requests that have whitespace characters in the URI
Built Option	Default
Usage	uri_whitespace action
Default	uri_whitespace strip

When the requested URL's contains whitespaces, them this tag is used to specify the action of Squid on that URL's. Actions are shown in the table below.

Actions:	
strip	The whitespace characters are stripped out of the URL. This is the behavior recommended by RFC2396.
deny	The request is denied. The user receives an "Invalid Request" message.
allow	The request is allowed and the URI is not changed. The whitespace characters remain in the URI. Note the whitespace is passed to redirector processes if they are in use.
encode	The request is allowed and the whitespace characters are encoded according to RFC1738. This could be considered a violation of the HTTP/1.1 RFC because proxies are not allowed to rewrite URI's.
chop	The request is allowed and the URI is chopped at the first whitespace. This might also be considered a violation.

Arguments

acion Action of Squid on identifying the white spaces

Example(s)
uri_whitespace deny

TAG NAME broken_posts

Description	A list of ACL elements which, if matched, causes Squid to send an extra CRLF pair after the body of a PUT/POST request
Built Option	Default
Usage	broken_posts allow deny aclname
Default	none

Squid will send an extra CLRF pair after the body of a PUT/POST request for the access list specified is matched. Some HTTP servers has broken implementations of PUT/POST, and rely on an extra CRLF pair sent by some WWW clients.

Arguments

allow/deny	Allow or deny access list
aclname	Access list name

Example(s)

acl buggy_server url_regex ^http://.... broken_posts allow buggy_server

TAG NAME	mcast_miss_addr
Description	When enabled, every "cache miss" URL will be sent out on the specified multicast address
Built Option	-DMULTICAST_MISS_STREAM
Usage	mcast_miss_addr ip_address
Default	mcast_miss_addr 255.255.255.255

Synopsis

You will be needing the "cache miss" URL to be sent on a specified multicast address. This tag provides the option.

Do not enable this option unless you are are absolutely certain you understand what you are doing.

Arguments

ip_address	ip address through which the URL to be sent
------------	---

Example(s)

mcast_miss_addr 172.16.1.255

Synopsis

The value specified in this tag specifies the time-to-live period for packets multicated when multicasting off cache miss URLs is enabled. By default this is set to 'site scope', i.e. 16.

Arguments

time-units Time to Live period

Example(s)

mcast_miss_ttl 10

TAG NAME	mcast_miss_port
Description	Used to define the port number to be used in conjunction with mcast miss addr.
Built Option	-DMULTICAST_MISS_STREAM
Usage	mcast_miss_port portnumber
Default	mcast_miss_port 3135

Synopsis

Port to be used for mcast_miss_addr.

Note: This tag is used only when you enable $mcast_miss_addr$.

Arguments

portnumber Port number on which Squid binds the socket

Example(s)

mcast_miss_port 3100

TAG NAME	mcast_miss_encode_key
Description	This is the encryption key used in the multicast miss stream
Built Option	-DMULTICAST_MISS_STREAM
Usage	mcast_miss_encode_key key
Default	mcast_miss_encode_key XXXXXXXXXXXXXXXX

The URLs that are sent in the multicast miss stream are encrypted. This is the encryption key.

Arguments

Encription key to be used

Description	Enable/disable Squid to send non-hierarchial requests to parents
Built Option	Default
Usage	nonhierarchical_direct on off
Default	nonhierarchical_direct on

By default, Squid will send any non-hierarchical requests (matching hierarchy_stoplist or not cacheable request type) direct to origin servers. If you set this to off, then Squid will prefer to send these requests to parents. Note that in most configurations, by turning this off you will only add latency to this request without any improvement in global hit ratio. If you are inside a firewall then see never_direct instead of this directive.

Arguments

on/off Enable or disable sending non-hierarchal requests

TAG NAME	prefer_direct
Description	For enabling Squid to use parent if direct going is failed
Built Option	Default
Usage	prefer_direct on off
Default	prefer_direct off

Synopsis

Normally Squid tries to use parents for most requests. If you by some reason like it to first try going direct and only use a parent if going direct fails then set this to on.

By combining nonhierarchical_direct off and prefer_direct on you can set up Squid to use a parent as a backup path if going direct fails.

Arguments

on/off Enable or disable preferer_direct option

TAG NAME	strip_query_terms
Description	For tripping query items before logging
Built Option	Default
Usage	strip_query_terms on off
Default	strip_query_terms on

Synopsis

Squid by default does not log query parameters. These parameters are however forwarded to the server verbatim. If we want to enable logging of query parameters, the <code>strip_query_terms</code> directive can be used.

By default, Squid strips query terms from requested URLs before logging. This protects your user's privacy

Arguments

on/off Enable or disable query parameters from logging

TAG NAME	coredump_dir
Description	Squid leaves core files in the directory specified
Built Option	Default
Usage	coredump_dir directory
Default	coredump_dir none

Synopsis

By default Squid leaves core files in the directory from where it was started. If you set *coredump_dir* to a directory that exists, Squid will chdir() to that directory at startup and coredump files will be left there.

Arguments

directory Directory for used for core dump

Example(s)

coredump_dir /usr/local

TAG NAME	redirector_bypass
Description	Used for bypassing the request
Built Option	Default
Usage	redirector_bypass on off
Default	redirector_bypass off

Synopsis

When this is 'on', a request will not go through the redirector if all redirectors are busy. If this is 'off' and the redirector queue grows too large, Squid will exit with a FATAL error and ask you to increase the number of redirectors. You should only enable this if the redirectors are not critical to your caching system. If you use redirectors for access control, and you enable this option, then users may have access to pages that they should not be allowed to request.

Arguments

on/off Enable or disable redirector_bypass

TAG NAME ignore_unknown_nameservers

Description	Enable or disable responses from unknown nameservers
Built Option	Default
Usage	ignore_unknown_nameservers on off
Default	ignore_unknown_nameservers on

By default Squid checks that DNS responses are received from the same IP addresses that they are sent to. If they don't match, Squid ignores the response and writes a warning message to cache.log. You can allow responses from unknown nameservers by setting this option to 'off'.

Arguments

on/off Enable or disable

TAG NAME	digest_generation
Description	This controls whether the server will generate a Cache Digest of its contents
Built Option	enable-cache-digests
Usage	digest_generation on off
Default	digest_generation on

Synopsis

This tag enables or disable the server generating a cache digest of its contents. By default, Cache Digest generation is enabled if Squid is compiled with USE_CACHE_DIGESTS defined.

Arguments

Enable or disable the server generating a cache digest of its contents

on/off

TAG NAME	digest_bits_per_entry
Description	Defines number of bits of server's cache digest to be associated with the digest entry
Built Option	enable-cache-digests

Usage digest_bits_per_entry number Default digest_bits_per_entry 5

Synopsis

This is the number of bits of the server's Cache Digest which will be associated with the Digest entry for a given HTTP Method and URL (public key) combination.

Arguments

Number of bits per entry number

Example(s)

digest_bits_per_entry 5

TAG NAME	digest_rebuild_period
Description	This is the number of seconds between Cache Digest rebuilds
Built Option	enable-cache-digests
Usage	digest_rebuild_period time(seconds)
Default	digest_rebuild_period 1 hour

Synopsis

This tag defines the time period between successive cache digest rebuilds.

Arguments

time Time period between rebuilds

Example(s)

digest_rebuild_period 2 hour

I AG NAME	algest_rewrite_period
Description	This is the number of seconds between Cache Digest writes to disk.
Built Option	enable-cache-digests
Usage	digest_rewrite_period time(seconds)
Default	digest_rewrite_period 1 hour

Synopsis

This tag specifies the time period between successive writing to disk by cache digest .

Arguments

time Time period between successive writes

Example(s)

digest_rewrite_period 2 hour

TAG NAME digest_swapout_chunk_size

Description	This is the number of bytes of the Cache Digest to write to disk at a time
Built Option	enable-cache-digests
Usage	digest_swapout_chunk_size bytes
Default	digest_swapout_chunk_size 4096 bytes

Using this tag, total number of bytes to be written to the disk at a time by the cache digest is specified.

Arguments

bytes	Total number of bytes to be written to the disk in single time

Example(s)

digest_swapout_chunk_size 2048 bytes

TAG NAME	digest_rebuild_chunk_percentage
Description	This specifies the percentage of the Cache Digest to be scanned at a time
Built Option	enable-cache-digests
Usage	digest_rebuild_chunk_percentage percent(0-100)
Default	digest_rebuild_chunk_percentage 10

Synopsis

Using this tag, we can specify the percentage of the cache disgest to be scanned at a time.

Arguments

percent	Percentage of cache digest to be scanned at a time	
percent	Percentage of cache digest to be scanned at a time	9

Example(s)

digest_rebuild_chunk_percentage 20

TAG NAME	chroot
Description	Use this to have Squid do a chroot() while initializing
Built Option	Default
Usage	chroot
Default	none

Synopsis

Squid by default does not fully drop root privileges because it may be required during reconfigure. So use this directive to have Squid do a chroot() while initializing. This also causes Squid to fully drop root privileges after initializing. Squid only drops all root privilegies when chroot_dir is used. Without chroot_dir it runs as root with effective user nobody. This means, for example, that if you use a HTTP port less than 1024 and try to reconfigure, you will get an error.

Example(s)

chroot

TAG NAME	client_persistent_connections, server_persistent_connections
Description	Enable/disable persistent connection support for clients and servers
Built Option	Default
Usage	client_persistent_connections on off server_persistent_connections on off
Default	client_persistent_connections on server_persistent_connections on

Synopsis

By default, Squid uses persistent connections (when allowed) with its clients and servers. You can use these options to disable persistent connections with clients and/or servers.

Arguments

on/off	Enable or disable persistent connections	

	TAG NAME	persistent_connection_after_error
0	escription	With this directive the use of persistent connections after HTTP errors can be disabled.
E	Built Option	Default
ι	Isage	persistant_connection_after_error on off
	Pefault	persistent_connection_after_error off

Synopsis

With this directive the use of persistent connections after HTTP errors can be disabled. Useful if you have clients who fail to handle errors on persistent connections proper.

Arguments

on/off	Enable or disable persistent connection after error

Description	Enables Squid attempts to detect the broken replies and automatically assume the reply is finished after 10 seconds timeout.
Built Option	Default
Usage	detect_broken_pconn on off
Default	detect_broken_pconn off

Some servers have been found to incorrectly signal the use of HTTP/1.0 persistent connections even on replies not compatible, causing significant delays. This server problem has mostly been seen on redirects.

By enabling this directive Squid attempts to detect such broken replies and automatically assume the reply is finished after 10 seconds timeout.

Arguments

on/off Enable or disable the detection of broken persistant connections

TAG NAME	balance_on_multiple_ip
Description	Enables to preserve user session state across requests to different IP addresses.
Built Option	Default
Usage	balance_on_multiple_ip on off
Default	balance on multiple ip on

Synopsis

Some load balancing servers based on round robin DNS have been found not to preserve user session state across requests to different IP addresses.

By default Squid rotates IP's per request. By disabling this directive only connection failure triggers rotation.

Arguments

on/off Enable or disable the balancing of multiple IP's

TAG NAME	pipeline_prefetch
Description	Used to boost the performance of pipelined requests to closer match that of a non-proxied environment
Built Option	Default
Usage	pipeline_prefetch on off
Default	pipeline_prefetch off

Synopsis

Squid can try to fetch up to two requests in parallell from a pipeline. Defaults to off for bandwidth management and access logging reasons.

Arguments

on/off Enable or disable pipeline prefetch

	TAG NAME	extension_methods
D	escription	You can add up to 20 additional request "extension" methods here for enabling Squid to allow access unknown methods
В	Built Option	Default
U	Isage	extension_methods methods
D	Pefault	none

Synopsis

Squid only knows about standardized HTTP request methods. Unknown methods are denied, unless you add them to this tag.

Arguments

methods New methods

Example(s)

extension_methods SEARCH

TAG NAME	request_entities
Description	Set this directive to on if you have clients which insists on sending request entities in GET or HEAD requests
Built Option	Default
Usage	request_entities on off
Default	request_entities off

Synopsis

Squid defaults to deny GET and HEAD requests with request entities, as the meaning of such requests are undefined in the HTTP standard even if not explicitly forbidden. Set this directive to on if you have clients which insists on sending request entities in GET or HEAD requests

Arguments

on/off Enable or disable

high_response_time_warning

Description	Enables Squid to print a WARNING to get the administrators attention
Built Option	Default
Usage	high_response_time_warning time(msec)
Default	high_response_time_warning 0

If the one-minute median response time exceeds this value, Squid prints a WARNING with debug level 0 to get the administrators attention. The value is in milliseconds.

Arguments

time Time after which warning is printed

Example(s)

high_response_time_warning 20

TAG NAME	high_page_fault_warning
Description	Enables Squid to print a WARNING to get the administrators attention
Built Option	Default
Usage	high_page_fault_warning time
Default	high_page_fault_warning 0

Synopsis

If the one-minute average page fault rate exceeds this value, Squid prints a WARNING with debug level 0 to get the administrators attention. The value is in page faults per second.

Arguments

Time after which warning is printed time

Example(s)

high_page_fault_warning 10

TAG NAME	high_memory_warning
Description	Enables Squid to print a WARNING to get the administrators attention
Built Option	enable-snmp
Usage	high_memory_warning number
Default	high memory warning 0

Synopsis

If the memory usage (as determined by mallinfo) exceeds value, Squid prints a WARNING with debug level 0 to get the administrators attention.

Arguments

time Time after which warning is printed

Example(s)

high_memory_warning 20

TAG NAME	store_dir_select_algorithm
Description	Used to specify the algorithm for store directory selection
Built Option	enable-snmp
Usage	store_dir_select_algorithm algorithm-type
Dofault	store dir colect algorithm least lead

Synopsis
As there are more number of store directories, this tag allos you to specify the algorithm by which Squid will select the store directories.

Arguments

algorithm-type Algorithm to be used

Example(s)

store_dir_select_algorithm round-robin

TAG NAME	forward_log	
Description	Logs the server-side requests.	
Built Option	enable-forward-log	
Usage	forward_log path	
Default	none	

Synopsis

Logs the server-side requests.

Arguments

path

Path to the forward Log file

A	TAG NAME	ie refrest

Description	Turning this on provides a partial fix to the problem with Microsoft Internet Explorer up until version 5.5 Service Pack 1 which has an issue with transparent proxies, wherein it is impossible to force a refresh
Built Option	Default
Usage	ie_refresh on off
Default	ie_refresh off

Turning this on provides a partial fix to the problem, by causing all IMS-REFRESH requests from older IE versions to check the origin server for fresh content. This reduces hit ratio by some amount (~10% in my experience), but allows users to actually get fresh content when they want it. Note that because Squid cannot tell if the user is using 5.5 or 5.5SP1, the behavior of 5.5 is unchanged from old versions of Squid (i.e. a forced refresh is impossible). Newer versions of IE will, hopefully, continue to have the new behavior and will be handled based on that assumption. This option defaults to the old Squid behavior, which is better for hit ratios but worse for clients using IE, if they need to be able to force fresh content.

Arguments

on/off Enable or disable this feature

	TAG NAME	vary_ignore_expire
Desc	cription	This option enables Squid to ignore, immediate expiry time with no cache-control header when requested by a HTTP/1.0 client
Built	t Option	Default
Usag	ge	vary_ignore_expire on off
Defa	ult	vary_ignore_expire off

Synopsis

Many HTTP servers supporting Vary gives such objects immediate expiry time with no cache-control header when requested by a HTTP/1.0 client. This tag enables Squid to ignore such expiry times until HTTP/1.1 is fully implemented.

Note: This may eventually cause some varying objects not intended for caching to get cached.

Arguments

on/off Enable or disable vary_ignore_expire feature

A	TAG NAME	sleep_after_fork
	Description	When this is set to a non-zero value, the main Squid process sleeps the specified number of microseconds after a fork() system call
	Built Option	Default
	Usage	sleep_after_fork time(microseconds)
	Default	sleep_after_fork 0

Synopsis

This sleep may help the situation where your system reports fork() failures due to lack of (virtual) memory. Note, however, that if you have lot of child processes, then these sleep delays will add up and your Squid will not service requests for some amount of time until all the child processes have been started.

Arguments

time Sleep time period

Example(s)

sleep_after_fork 20

TAG NAME	minimum_expiry_time
Description	The minimum caching time according to (Expires - Date)
Built Option	Default
Usage	minimum_expiry_time time(seconds)
Default	minimum_expiry_time 60 seconds

Synopsis

The minimum caching time according to (Expires - Date) Headers Squid honors if the object can't be revalidated defaults to 60 seconds.

In reverse proxy enorinments it might be desirable to honor shorter object lifetimes. It is most likely better to make your server return a meaningful Last-Modified header however.

Arguments

time Expiry Time

Example(s)

minimum_expiry_time 120 seconds

TAG NAME	relaxed_header_parser
Description	Squid accepts certain forms of non-compliant HTTP messages where it is unambiguous what the sending application intended even if the message is not correctly formatted.
Built Option	Default
Usage	relaxed_headre_parser on off
Default	relaxed_header_parser on

In the default "on" setting Squid accepts certain forms of non-compliant HTTP messages where it is unambiguous what the sending application intended even if the message is not correctly formatted. The messages is then normalized to the correct form when forwarded by Squid.

Arguments

off	A warning will be emitted in cache.log each time such HTTP error is encountered.
warn	HTTP errors will cause the request or response to be rejected.

Example(s)

relaxed_header_parser warn
